SILVERS.—The noblest of the silvers is the variable S. Cotyledon, a grand plant, with beautiful foliage and fountains of white flowers, the better part of a yard in height; it shall be represented

A SHEET OF DAZZLING WHITE BETWEEN PATH AND STREAM.
An informal ribbon edging of one of the mossy rock foils.

Digitized by Google

by the fine varieties pyramidalis and caterhamensis. Then the remarkable S. longifolia, with its great leaf-rosettes, must have a place, although it is monocarpic and a little disappointing in flower. The Hostii group must be included, notably the var. altissima, quite a yard in height. Then we can get away from the prevailing white of the flowers of the "silvers" by including the pink cartilaginea var. Kolenatiana. The valuable S. lingulata must not be omitted, and we shall take vars. lantoscana and Albertii as being about the best. Neither can S. cochlearis be left out, var. major being given precedence, while instead of var. minor we shall take the minute S. valdensis, as dainty as a tiny Kabschia; but see that you get the right thing, not cochlearis minor, which often masquerades as valdensis. Then the polymorphic S. Aizoon must be included, and by choosing vars. balcana, lutea and rosea we shall get away from the monotony of white blossoms. Finally, we may add two excellent crosses, S. splendens (longifolia × Cotyledon) and S. paradoxa (crustata × Hostii). This selection will give us about the best of the silvers, as well as a wide range as regards size and habit.

KABSCHIAS.—In this group we get a diminished range of form, for all are small and tufted, but a greater variety of colour, since there are plenty of yellows and reds in addition to whites. These are the rock saxifrages *par excellence*, and their close, often tiny tufts are the most charming things imaginable. A few are difficult, and in other cases it is almost impossible to get the true plants, but there remains a large number of charming things from which to make our selection. This group has been hybridised by growers to an excessive extent. Many of these crosses are real good things, but many others are not preferable to their parents, and some of the most high-sounding and unpronounceable names need not be allowed to take us in, for the names are the most striking things about them.

Well, first of all there are four plants which for vigour, ease of cultivation and general satisfactoriness stand in the forefront—apiculata, its var. alba, sancta and Elizabethæ (and, as if to refute what I have just said, all of them but sancta are hybrids). None of the other Kabschias is capable of making a mat the better part of a yard across, nor of existing under such unfavourable conditions as these can. All but the second are yellow, of different shades. Of many other yellows from which we may choose, perhaps the best, taken all round, are Ferdinandi-Coburgi, the lovely Faldonside, the pale Borisii set off by the vivid Haagii, and the dainty Paulinæ (if you are lucky enough to get the right thing). Then of whites, we must have at least one Burseriana, that best of Kabschias, and a good form of var. major cannot be beaten. S. cæsia is dainty and easy. S. marginata must have a place, say, in its var. Rocheliana; scardica and Petraschii are delightful; and we may close with two tinies, tombeanensis and squarrosa. Of the reds, a very striking group of small rosette-forming plants, Grisebachii and Stribnryi, with their fluffy flower-heads, are representative; and our list must close with the dainty pink Irvingii and the lilac-flowered lilacina—both unique in their coloration.

The MOSSIES need not detain us long. Normally white flowered, the red flowers of moschata atropurpurea gave raisers a chance of which they were not slow to avail themselves, so that now we have a whole range of reds from pink on to deep velvety crimson. And—joy of joys—all are as easy and vigorous as one could desire, and in contrast to the Kabschias, which want all the sun they can get, they rejoice in half-shade. Of the reds, we may select sanguinea superba, Red Hussar and the dainty pink atropurpurea Stormonth's variety (I do not feel sure about the parentage of these, so omit specific names). The original moschata atropurpurea is very dwarf and pleasing. Of the whites, S. Camposii (= Wallacei) must take a high place. Then there are two very fine strong things, trifurcata and its var. ceratophylla, which make grand cushions and have the advantage of coming in when most of the saxifrages are over; and, finally, S. tenella is very dainty and different in appearance from the rest.

MISCELLANEA.—We now come to the fourth and last division of our fifty saxifrages, the miscellaneous plants, drawn from several sections of the genus, which will round off the series, and impart further variety to our selection of silvers, Kabschias and mossies. We may first call on the Robertsonia or London pride group, for these are really lovely plants, though extreme familiarity tends to blind us to their beauty. S. umbrosa primuloides, with its tiny hairy rosettes and pink flowers, is the daintiest of the London prides, and with it we may bracket the boldly toothed form Colvillei. The valuable hybrid Andrewsii will make a good third. The monotypic section Xanthozoon consists of S. aizoides, of which the deep red var. atrorubens is one of the best of saxifrages, and eminently suitable for a damp corner. The section Porphyrion includes three species, of which two, retusa and oppositifolia, are quite essential to our selection. Of the former we take var. grandiflora, which, properly grown, will make a sheet of royal purple in April. It and the little dainty rosy-flowered retusa introduce a welcome change from the whites and yellows which prevail among the saxifrages. The Diptera section also supplies a novelty in the shape of rather large palmate leaves and loose butterfly-like sprays of white flowers with one or two long petals hanging down far beyond the others. We must have S. Fortunei, and we should plant it in a cool, shady spot, for it likes moisture and does not flower till October, when early frosts may injure it. Only one place is now left among our fifty, and it may well go to the tiny S. Brunoniana, with its web of thread-like red stems spreading over the ground—a most dainty and unusual saxifrage.

It has taken us a good while to make our selection of fifty best saxifrages—I hesitate to say *the* fifty best—but there it is for my readers to pull to pieces, and I shall conclude by giving the list in alphabetical order.

Saxifraga aizoides var. atrorubens
Aizoon var. balcana
A. var. lutea
A. var. rosea
Andrewsii
apiculata
a. var. alba
Borisii
Brunoniana
Burseriana var. major
cæsia
Camposii
cartilaginea var. Kolenatiana
cochlearis var. major
Cotyledon var. caterhamensis
C. var. pyramidalis
decipiens var. Red Hussar
d. var. sanguinea superba
Elizabethæ
Faldonside
Ferdinandi-Coburgi

umbrosa var. Colvillei
u. var. primuloides
valdensis.

CORRESPONDENCE

PRIMULA SUCCESSES AND FAILURES.

SIR,—What I think is so very interesting and makes one wonder, are the reasons for the successes and failures of different people in growing primulas. I should like to add a few notes as I grow various kinds in a stream garden, partially shaded by rhododendrons and oaks.

P. chionantha, I find, requires a piece of glass over it in winter as the plants without it all rotted. P. Palinuri was also glassed over as I have it on the level, elevated above the bog. It is now in flower, with the glass removed. I found that taking up and dividing P. secundiflora after flowering seemed to save it from rotting. P. lichiangensis died this winter, largely through my own fault. It needs glass in a damp garden. P. Loczii is quite hardy if in a suitable position. It must have peat, leaf-mould and sand and a moist position. It is an attractive little primula just coming into flower now.

P. anisidora seems quite hardy, likes rich potting soil and an open position. P. Littoniana does not like much sun, it prefers a cool, peaty shady position.

I find P. sikkimensis longer lived on a sloping rather than flat bog. I lost several plants of P. frondosa last autumn by rotting. I promptly put glass over the rest and saved them.

P. Giraldiana seems impossible. It rots at once after flowering. P. helodoxa likes light rich soil and a cool position; it is very easy. P. luteola is a delightful plant with its mop of yellow flowers; it likes deep, rich, light soil, a cool position, but not wet; it is quite hardy.

The severe winter was too much for P. Poissoni. It was growing in wet bog and held out for a long time, but finally succumbed. I shall grow it again and protect it in winter.

I find P. deorum perfectly hardy and have it on the edge of the pond and on an elevated position above the bog, both doing well. It appears to me that the critical time for many primulas is after flowering, say August or September, when they want to ripen their leaves and form crowns for the next year,

Digitized by Google

and if one puts glass over them at this time they are saved from rotting.

Two primulas that do not mind being submerged by winter floods are P. pulverulenta and P. cashmeriana. The thermometer registered zero once by the stream this winter and we had 15ins. of snow.—D. D. V., *Newbury*.

VARIETIES OF GREENHOUSE PRIMULAS.

SIR,—Although there is a large number of primulas to select from, in all probability the P. stellata varieties are the most popular. The plants are vigorous, light and graceful, and their flowering is spread over a fairly long period. Three varieties are illustrated from plants grown at Castleford, Chepstow. Reading from left to right, they are Ruby, a richly coloured primula; Light Blue, with fairly large porcelain blue flowers; and Coral Pink, a pretty shade of creamy pink, and it is one of the best primulas in commerce. Other good forms embrace Silver Star, a pure white variety; Vesuvius, a brilliant crimson; and Symmetry, a rich rose pink and an exceptionally strong grower. All the above are Messrs. Sutton's varieties, and the plants in the illustration were grown from their seeds. There is also a fine selection of P. sinensis, such as The Duchess, Coral Pink, blue, and white. For those who can handle P. obconica, a good mixed strain is very profitable; there are also some distinct varieties of this fine primula. The exquisite P. malacoides must not be forgotten, or the beautiful yellow P. kewensis. Many of the hardy primulas make excellent cool greenhouse subjects. An additional charm of greenhouse primulas is the foliage and the striking colour of the leaf stalks and flower stems.—T. W. B.

HARDINESS OF SHRUBS.

SIR,—Some of the recent notes on the hardiness of shrubs, flowering and evergreen, have been most interesting.

Last week a Somerset correspondent wrote that in the north of that county Garrya elliptica and Desfontainea spinosa suffered at times. I have known those come through quite bad weather in the south of Forfarshire. It is true they were planted against a wall within 500yds. of high tide and about 100ft. above sea level. The bush of Garrya elliptica must now be more than sixty-five years old, but the other plant had to be renewed more than once. In the same garden I grew and flowered Notospartium Carmichaeliæ and Olearia macrodonta.

Here, where the conditions are less favourable, as I am six miles from the sea, with an intervening ridge of low hills, the frost is much more intense, but this winter I have been astonished at the way some plants have escaped injury and am comparing my experience with the article by "A. T. H." in THE GARDEN of February 27th, page 126.

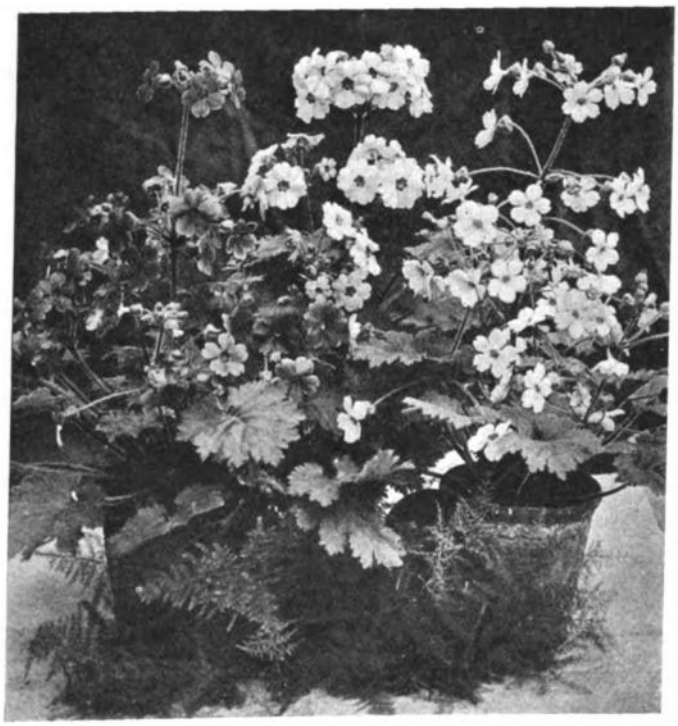
Choisya ternata, Escallonia macrantha, Notospartium Carmichaeliæ, Buddleia alternifolia, and the common rosemary, all growing on or near walls, have escaped injury. The common myrtle, however, has been badly scorched, but is not dead. Lonicera nitida has been grown here in an exposed position for twelve years and I have it growing as a hedge as well.

The immunity to frost damage this winter is due to the weather, a comparatively dry October, frost beginning about November 8th, never very severe until just at the end of December (26th), when the minimum fell to 7 degrees F.—25 degrees of frost! The severe frost was accompanied by dry, light snow, which itself was a great protection. Had the autumn been wet and the frost severe to begin with, the result would have been different.

I can just manage Olearia Haastii here; it gets cut to the ground occasionally, but pushes away again from the root, provided there is no peat in the soil where it is planted. —WILLIAM LOW, *Montrose*.

ROSE ZEPHIRINE DROUHIN.

SIR,—I was much interested in Mrs. E. H. Palmer's account, in THE GARDEN of February 20th, of the Rose Zéphirine Drouhin. I have grown it for years and am also surprised that so few people know it. I have four large plants each in a different situation and all doing equally well. There is just one further attraction which might be added to the list with which Mrs. Palmer so justly endows it. Although quite a good



PRIMULA STELLATA AND ITS VARIETIES.

pink by daylight, by artificial light (at all events by lamplight, which I have in my old-fashioned house), the colour becomes almost startling in its brilliant vividness. It has then a living, glowing quality which makes it quite unique.

The foliage with me is almost evergreen and the bushes look well all the winter.—MRS. R. E. VERNEDE, *Standon, Herts*.

THE HARESFOOT FERN.

SIR,—I think it may interest your readers to have an account of a fine specimen of the Haresfoot fern, Davallia canariensis, which has been in the possession of our family between forty and fifty years. My late mother-in-law's gardener remembers it as a small plant in a 7in. pot, in the summer of 1882. About the next spring he potted it on into a 10in. pot, and it was not potted afterwards. It did so well that in the summer of 1896, when it was photographed, it was about 20ft. in circumference. The old fronds were (and still are), cut off annually, when the new fronds began to show in the spring. It was then given a sprinkling of Clay's Fertiliser, worked in among the "feet" and fed regularly with liquid manure about twice a week, till it had finished its growth. The fern remained in the same pot, which was almost hidden from sight, until about eight years ago, when it fell off the pot, having quite outgrown it. Being of such bulk it was impossible to re-pot it, but since then the fern has continued to live quite happily, resting on a pot, living without soil, simply depending on water and chemical manure. I regret that I am unable to send a photograph of this fine plant, which appears to be still in good health, though it is not so large as it was ten years ago.—ANNIE C. BULLEY, *Painswick, Glos.*

SHRUBBY VERONICAS AND FROST.

SIR,—I was much interested in the note by E. Brown of Sittingbourne, Kent, in your issue of February 27th, on "Shrubby Veronicas and Frost."

In this part of the country we have had a very hard winter, with severe frosts, in spite of which I find that none of my shrubby veronicas has suffered at all. I have been growing the following dwarf varieties, and find they have come unscathed through the last three winters with all their variations of rain and cold: VV. salicornoides, cupressoides, buxifolia, Hectori, decumbens and pinguifolia. My soil is very sandy, and the veronicas are planted in the rock garden, and are exposed to all the winds of a very stormy neighbourhood. In spite of our position on the east coast of Scotland, I find various so-called half-hardy plants are thoroughly at home, such as Cistus cobariensis, Helichrysum bellidioides, Bellis coerulescens rotundifolia and Nierembergia rivularis; and, while the following three may suffer a little from the frost, they all come up freely from the root: Antirrhinum Asarina, Abronia arenaria and Æthionema cordifolia.

We have a drier climate than many parts of the country; to which (and my sandy soil) I always attribute the hardiness of various species which suffer more in the milder, damper winters of the west coast.—M. FORREST MILL, *Montrose, Scotland*.

PLANTING SEEDS.

SIR,—Mr. J. R. Matthews' article and accompanying illustrations in THE GARDEN of February 27th in relation to the planting of large seeds is very interesting and descriptive of what takes place on the germination of seed and the commencement of growth.

He asks other readers to give the results of their observations and experience in that direction.

For my own part, I really could not go into any scientific detail on the germination of the various kinds of seeds which I have noticed, apart from those Mr. Matthews has mentioned, such as beans, etc. It is well known to most cultivators, however, that the seeds of melons, cucumbers and marrows give a higher percentage of plants and better results if these large, flat, thin seeds are placed in the soil with the thin side or end down, than they would if placed on their flat side.

The large flat seeds of Grevillea robusta form another example of where a much higher percentage of plants is obtained if the seeds are placed on edge before covering with soil.—WM. GRANT, *Crathes, Kincardineshire, N.B.*

NOTES OF THE WEEK

THE AMAZON LILY.

(EUCHARIS AMAZONICA GRANDIFLORA.)

THIS is a charming greenhouse plant and is extremely useful, for it blooms at a time of year when flowers are scarce, and, furthermore, its beautiful pure white waxy flowers are appreciated for decoration. It has a peculiar habit of growth, for it may receive the same kind of treatment at two different establishments and will probably flourish luxuriantly at one place, while at the other it is a failure. One reason for this is that the bulbs are liable to be attacked by eucharis mite, and although certain preventive measures, such as an application of lime and soot in equal parts occasionally, may help to check the pest somewhat, it certainly does not cure, and in the long run the only remedy to prevent the pest from spreading is to burn all bulbs affected. When an abundant supply of heat is available, propagation may be done at any time, but as a rule it is advisable to wait until after the flowering period is over and the plants have been given a short period of rest. Old plants should be turned out of their pots and the bulbs carefully separated, the largest being selected for repotting. The small bulbs may be grown in 6in. pots into flowering-size bulbs for another season. A suitable compost should be made up as follows: Two parts fibrous loam broken up into pieces about the size of a hen's egg, one part leaf-soil, one part dried cow manure and sufficient sand to make the whole porous. Into 10in. pots a plentiful supply of drainage should be put, for the plant is a moisture-loving subject and good drainage is essential for good culture. Fill up the pots with two-thirds of compost and work it down moderately firm before setting the bulbs. The bulbs should be set about 3ins. apart and about five bulbs to each pot will be sufficient. In potting, ample room should be allowed for watering. After potting, remove the pots to a greenhouse where a bottom heat of 80° is maintained. This will greatly assist in speeding up the root action so that the plants will quickly become established. Careful watering is necessary at all times. The plants will only need keeping just nicely moist until the flowering period starts, when an abundance of water must be given regularly, also an occasional syringing will prove beneficial. To induce the plant to flower at any particular time the temperature must be reduced. A temperature of about 65° should be aimed at during the flowering period. Established plants will flower in the same pots for four or five years without being interfered with and, as a matter of fact, the less the roots are disturbed the better, but a top-dressing should be given them every year.—G. BARTON.

DAFFODILS AT THE NEW YORK BOTANIC GARDEN.

THE recent ruling of the Secretary of Agriculture of the United States, not to postpone the embargo on narcissi, has shown that the decision of Mr. Nathaniel L. Britton, Director of the New York Botanic Garden, to make a considerable planting of these bulbs in a location and manner which would show their beauty and effectiveness to the large numbers of people who visit the Gardens in the early spring, was a wise one. About forty-eight thousand bulbs in a large number of varieties were put in during the autumn of 1924 in a portion of the grounds eminently suited for such a collection and where there were already growing some thousands of large trumpet varieties. During the blooming season of 1925 the display was so successful that it was decided to add to the planting, and thirteen thousand additional bulbs were obtained and put in. The site chosen is adjacent to the original collection and follows both sides of a drive-way all the way out to an entrance to the Gardens. The daffodils have been "naturalised," so that the effect will not be stiff, and strong spots of yellow have been concentrated where they will attract the attention of passing motor cars on two main highways just outside the grounds.—ETHEL ANSON PECKHAM, *New Rochelle, N.Y.*

A SPRINGTIME DISPLAY IN THE NEW YORK BOTANIC GARDEN.

IPOMŒA RUBRO-CŒRULEA HEAVENLY BLUE.

THIS fine plant is closely associated with the convolvulus or bindweed family, and if a free-flowering strain of the variety Heavenly Blue is procured, good flowering examples can be had in three or four months from sowing the seed. It is a plant that is highly prized on account of its pure sky blue convolvulus blooms, which open in the morning, when a well flowered plant is a sight to behold. No written description or photograph can do it justice, and it has received the popular and suitable sobriquet of Morning Glory.

For several years I was greatly disappointed with the results attained in its cultivation. Seeds were bought from several reliable firms, and they germinated freely and grew like weeds, but no flowers appeared. After making enquiries, I found that in all probability Ipomœa Learii was doing duty for the subject of this note.

A few years ago, however, at the Chelsea Show, a kind friend gave me a plant of the true Heavenly Blue variety, and since then I have saved my own seed, with excellent results. It would be interesting to know if any reader still receives the non-flowering form, because I have every reason to believe that several firms now sell seeds of the right variety, usually under the name of I. rubro-cœrulea Heavenly Blue early-flowering.

Seeds should be sown now, and for succession a few more could be planted two months hence. It can also be increased by cuttings. Seeds will germinate in a temperature of 60°, but care must be taken to prevent the soil becoming wet, or many of the seeds will decay. Being a climber, suitable positions must be chosen for the plant to display its full beauty, and any greenhouse, warm or cool, will suit it; while a few plants could be tried outside in warm, sunny situations. The end of a greenhouse is a good place, and it can also be trained to pillars or on the roof, but if the latter is chosen the house should be a low one, so that the flowers could be seen from the outside. When trained to the roof of high structures, most of the exquisite beauty is lost, as the flowers open towards the light. They are very effective when trained as balloons, and the thoughtful grower will fine many corners where plants will ornament an otherwise bare place during the summer months. It should be treated as a greenhouse annual, and pots 6ins. and 8ins. in diameter will suit them admirably. Give them a generous rooting medium, and, when the receptacles are filled with roots, a weekly application of fertiliser or liquid manure will prolong the flowering period. Use the syringe occasionally to keep down red spider.

All this beautiful greenhouse annual requires is a few twigs or string to which it can cling, and a liberal diet. It is said that good wine needs no bush; but to those who have never grown it, my advice is, give it a trial.—T. W. BRISCOE.

ZAUSCHNERIA CALIFORNICA.

THIS plant is a native of California and Mexico, and is known as the Californian fuchsia and humming-bird's trumpet. It grows from 12ins. to 18ins. high, has small rather hairy leaves, and loose spikes of bright vermilion flowers which are produced during the late summer and autumn. It is a showy, hardy plant that will thrive in any good soil rather on the light side, and is well adapted for an open position on the rock garden, flowering at a period when the majority of plants are past their best.

The growths die down for the winter, when a light top-dressing of leaf-mould is beneficial. Old plants can be lifted and divided in the spring, and the stock may also be increased by cuttings of the young side shoots in September.

Perhaps in cold parts of the country it may be advisable to propagate a few plants annually and winter them in a cool greenhouse or frame, transferring them to their flowering quarters in the spring.

I have met with two varieties of Z. californica, *viz.*, mexicana and splendens, but they are little improvements on the type.—T. B., *Glos.*

Glass House Building

THE building and designing of Glass Houses is a highly specialised work—that is, if the structure is to be correctly designed and built to last.

In dealing with the firm of Duncan Tucker & Sons, Ltd., you are obtaining the combined experience of many years devoted exclusively to the erection of every form of Glass House ranging from the modest "Lean-to" to the expansive Winter Garden.

Whether your enquiry is for renovating an existing Glass House or designing a new one you will receive the same courteous and prompt attention.

IF you are contemplating the erection of a Glass House we should be glad to send you interesting and helpful literature to aid you in your choice of a suitable structure.

THE CURIOUSLY FORMED FLOWERS OF THE CALIFORNIAN PITCHER PLANT.

AN INTERESTING BOG PLANT.

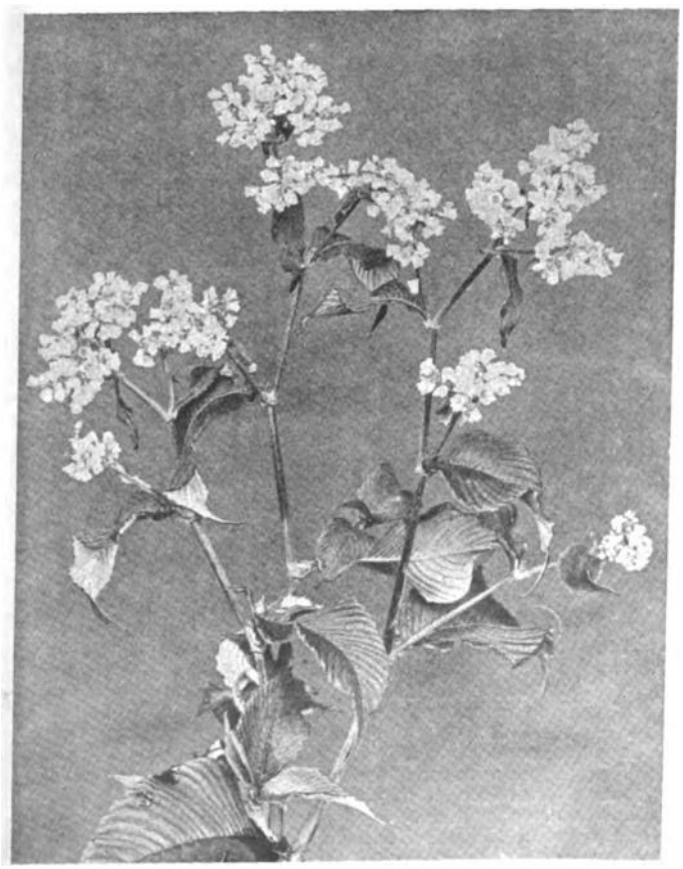
THE Californian pitcher plant (Darlingtonia californica), is one of the most interesting of the insectivorous species. The leaves, which rise to the height of 2ft. or more, are hollow and terminate in a curiously shaped hood from which hang two appendages. Most of the leaf is bright green, but, when mature, the hood assumes a red colour, relieved by semi-transparent areas. The darlingtonia, which is a native of the high bog tracts in the mountains of California, makes a most interesting plant for a sheltered bog garden. With care it is often less trouble to manage out of doors than under glass. An ideal situation is in a moderately wet bog where the soil is a mixture of fibrous peat and sphagnum moss. It is important that the plants be fully exposed to direct sunlight, but some protection should be given against the cold winds of the spring, at which season the darlingtonia is developing its leaves. If there is the least tendency on the part of the bog to become dry during the summer, frequent waterings are essential. Most of the best darlingtonias in the open are those which have been planted in close proximity to a pool or a stream where there is no fear of water shortage. When the darlingtonia is well established it produces numerous side shoots and these, if taken away and potted, soon make good plants. Raising the plants from seed is a most tedious business, as in the first few years the seedlings develop very slowly. The flowers of the darlingtonia, which are borne in April, are yellow in colour and extremely curious in their formation.—S. LEONARD BASTIN.

GENISTAS.

OF shrubs that bring beauty and sweetness in their train in the greenhouse in the early days of spring, few can rival genistas, with their prodigality of yellow blossoms, almost reminding one of the pungency of an aloysia (lemon-scented verbena). Grown from cuttings taken with a "heel" and inserted in pans of sandy loam after plants have flowered, they soon develop into bushy little specimens and can be finally potted into 5in. or 6in. pots. Young plants furnish the finest spikes, but older plants need not of necessity be despised. The latter, however, if left too long in the same pot become impoverished at the roots; but root starvation may be obviated by taking away some of the old material and substituting a mixture of old turf and leaf-mould, with a little coarse silver sand. It will be within the recollection, doubtless, of not a few readers that genistas are hardy in many parts of the country, in Devonshire and Somerset, for instance. My mind reverts to a garden in north Wales where, near the doorway, two huge bushes have filled the air with fragrance in summer, these many years, and one wonders how these old stalwarts have fared during the severe weather we have experienced. There used to be some in the Conway Valley; perhaps Mr. A. T. Johnson could say whether these deserving shrubs have escaped in the arctic conditions they have had to contend with.—W. LINDERS LEA.

POLYGONUM CAMPANULATUM.

THIS attractive plant is a fine subject for the herbaceous border, being of special value because of its late flowering period. Of free growing habit, it forms a bushy plant from 2ft. to 3ft. in height, composed of numerous much-branched shoots. Its leaves are also very attractive and of varying shape, being either ovate, elliptical or lanceolate, and of a rich green colour, the under sides being thickly clothed with brown hairs. Its flowers are very profusely borne on terminal clusters, and are usually pale pink in colour, though sometimes of a considerable deeper shade, being produced throughout September and October. An introduction from the Himalaya, it is quite hardy and free-growing, thriving in any average garden soil.—A. G. F.



POLYGONUM CAMPANULATUM, AN ATTRACTIVE SUBJECT FOR THE HERBACEOUS BORDER.

AN UNUSUAL FERN FOR A HANGING BASKET.

PLATYCERIUM ALCICORNE.

THE platyceriums are epiphytic ferns, usually attaining a large size. Five or six species are in cultivation, the most widely grown being, probably, P. grande and P. alcicorne. Peculiar to this genus is the production of two kinds of leaves. In the subject of this note the fertile leaves are erect and narrow, forking at the tip into two or three lobes, on the under sides of which the sporangia are borne in dense, irregular masses. These leaves are of a bright, rich green colour above, and covered beneath by a soft, white felt. The sterile leaves cling to the object which affords the plant support. When young they are pale green and downy, later becoming stiff and brown. Near their bases they are rather fleshy and probably serve as water-storage organs; when decayed they supply a certain amount of humus to meet the future needs of the plant. The specimen shown in the illustration is a young plant growing in a hanging wooden basket on a block of fibrous peat, through which its roots penetrate to the bottom and sides, there producing numbers of young plants from adventitious buds. These can be removed and used for the purpose of propagation.—N. K. G.

RHODODENDRON CALOPHYTUM.

THIS is certainly one of the finest species. In places where there is plenty of moisture passing through, but not stagnant in the soil, it grows quickly. The leaves are often as much as 12ins. in length, and are peculiarly apt to twist and sway in wind, hence the need for shelter. When about ten years of age it commences to flower. The large trusses contain twenty or more flowers, each about 2ins. to 2½ins. across, bell-shaped, blush white with a deep blotch on the upper petals. The plant itself is apparently quite hardy, although the flowers opening in March are liable to be destroyed by severe frost.

Our largest plant is probably one of Wilson's first

Digitized by Google

introduction in 1904, and is now 7ft. in height and 11ft. through, bearing over one hundred trusses of flower this season. I only mention this as showing what is possible in Sussex. No doubt in more genial climates individual plants have already attained a much greater size. In its native China and Tibet it is said to reach a height of 50ft., but it has none of the tree-like appearance of R. arboreum in a young state. All the plants known to me are rounded and bushlike.—J. COMBER, *Nymans Gardens*.

CYMBIDIUMS AND SHRUBS AT VINCENT SQUARE

RARELY, if ever, has such a brilliant display been seen in the month of March at the R.H.S. Hall, Vincent Square, as was the case on the 9th and 10th inst., on the occasion of the ordinary fortnightly meeting. The Hall was filled with exhibits, as varied as they were beautiful, from almost all over the country. Cymbidiums were the principal feature, but flowering shrubs, carnations and bulbs were there in plenty and produced a wealth of colour, while alpines and cyclamen added to the general interest of the Show.

The largest exhibit was that of Azalea indica, shown by Messrs. L. R. Russell of Richmond. The plants were exceedingly well grown and carried masses of bloom. Many varieties in all shades were to be seen. Blushing Bride, a large-flowered, delicate pink was particularly good; Apollo was a striking orange scarlet; and President Oswald de Kerchove, a soft pink blotched with carmine. Messrs. Cuthbert and Co. showed a number of varieties of Azalea mollis × sinensis in varying tones of yellow, orange and orange salmon. Sybil, Hugo Koster, Hortulanus Witte, should be mentioned. Vice-Admiral Walker Heneage Vivian exhibited fine specimens of Rhododendron grande, R. Nivium hybrid and R. Falconeri × eximeum. Lady Loder's rhododendron exhibit was much admired. Good trusses of R. Thomsoni × arboreum Blood Red and R. sutchuenense were among the collection, and a spray of Magnolia Campbelli, carrying on its leafless branches several large and beautiful blooms of soft pink, attracted considerable attention. Sir John Ramsden and Messrs. Gill and Son, also showed a number of rhododendrons. R. Thomsoni × barbatum from the garden of Sir John Ramsden was a handsome specimen. Messrs. W. Cutbush and Messrs. R. Wallace, both had varied and interesting shrub collections.

A large group of hyacinths in pots was admirably staged by Messrs. Carter and Co. The varieties were arranged in patches of contrasting colours, which looked most effective. Perfect blooms of General Wetter, Moreno and Queen of the Blues were noted. Tulips were set in a large bed of moss by Messrs. Sutton and Son, such varieties as Prince de Ligne, Louis Pasteur and Van de Neer had been used. Messrs. R. H. Bath showed a number of tulips growing in bowls. Narcissi of all kinds were exhibited by several bulb specialists. Messrs. J. R. Pearson and Messrs. Barr and Son had interesting groups of new varieties and a number of fine seedlings. March Sunshine, Marshlight and Rosary were shown by the former, and Sweet Peggy, Tasse d'Or (a new jonquil hybrid), and St. Germans (a large trumpet daffodil), were noted on the stand of the latter. Messrs. Cartwright and Goodwin, Limited, and Messrs J. W. Barr, also showed narcissi.

A very beautiful group was formed by Mr. Dalrymple's coloured freesias. The great variety in shade and the delicacy in colour of these fragrant flowers were surprising. The best kinds were Buttercup, a golden yellow freesia of good substance; Treasure; Glowing Embers and Apotheose. Another group which showed the valuable work done by selection and hybridisation, was that of Mr. J. W. Forsyth's Caledonian Strain cyclamen, the popularity of which is becoming widespread.

The carnations exhibited were better in colour and form than usual. Mr. C. Engelmann showed a number of blooms of old and new varieties. Messrs. Allwood Bros. had good vases of Shot Silk, Wivelsfield Claret and Mary Allwood. Messrs. Stuart Low showed carnations and a number of greenhouse plants, such as acacias and hippeastrums. Messrs. Reamsbottom exhibited their famous St. Brigid anemones, Messrs. Bunyard a collection of apples, Mr. G. Miller primroses and polyanthus, and forced roses came from the nurseries of Mr. Elisha Hicks and Mr. George Prince. Violets were shown by Mr. Baldwin Pinney and Mr. J. J. Kettle.

Alpines were shown in great plenty and old favourites found no startling novelties to outshine them. Messrs. Prichard showed a fine deep coloured form of Primula denticulata, and an interesting group of new, unnamed hybrid saxifrages. Messrs. Tucker showed a very beautiful Primula tirolensis, a rounded flower of clear, pale lavender, and P. sinensis, similar in colour, but with rather starry petals. Clarence Elliott and Co. received an award of merit for a well flowered plant of the hybrid saxifrage "Arco-Valleyi," and exhibited a number of vigorous plants of the rare Primula Allioni.

Messrs. Jeans and Trowbridge, exhibiting for the first time, brought the interesting little heather, Erica hypnoides, a very compact mossy variety that suggests one of the very dwarf conifers and the uncommon Helionopsis breviscapa in pale purple and white.

Messrs. J. Robinson of Eltham, another newcomer, made a neat little miniature landscape with two small river valleys winding down from a mountain side, wooded with dwarf conifers.

In Messrs. Gavin Jones' garden a patch of rough grey scree showed up the bright magenta crimson of Saxifraga retusa and S. Frederici-Augusti, and a patch of turf made a natural background to the native, well known but hard to beat Anemone Pulsatilla. Messrs. Cheal showed the early-flowering white trillium, T. ovata, and a small fairy-like form of Primula farinosa, collected in Yorkshire but very like the variety known as "scotica."

Messrs. Reuthe exhibited some fine vigorous plants of Shortia galacifolia, lifted from the open, showing that this very beautiful woodlander is not necessarily difficult or hard to please. With it was shown another good plant for a cool corner, the ivory white, fragrant Daphne Blagayana from the Alps of Carniola.

Messrs. Barr showed a particularly fine hybrid hellebore, "Fairy Queen," a warm white with a delicately flamed central patch of pale purple, together with many choice small daffodils and the rare, gentian blue Tecophilæa cyanocrocus from Chile.

Messrs. Waterer showed Iris persica, that very old garden plant whose strange beauty of white and purple-black and aquamarine is not often seen in modern gardens; the natural hybrid daffodil "Queen of Spain," very elegant and distinguished; Tulipa præstans Tubergen's variety, a flaming orange scarlet; and the large, cool forget-me-nots of Omphalodes cappadocica.

AN IMPOSING GROUP OF CALEDONIAN STRAIN CYCLAMEN

Messrs. J. and A. McBean, Cooksbridge, Sussex, were awarded a gold medal for an exceptionally fine group of various cymbidium hybrids and odontoglossums. Other notable plants were Lycaste Skinneri var. Mrs. Hamilton Smith, the largest form yet seen; Phalænopsis Rimestadiana, with large moth-like flowers; the richly coloured Oncidium McBeanianum; Odontioda Thela, of bright scarlet red; and along the back some tall plants of Epidendrum Nebo, with clusters of bright rose coloured flowers.

Silver-gilt Banksian medals were awarded to Messrs. Sanders, St. Albans, for an extensive exhibit containing many superb cymbidiums, the rare Ærides Houlletianum and Brasso-Cattleya St. André, with pale green flowers, having a rose flushed lip. Messrs. Cowan and Co., Southgate, N., who also staged many excellent cymbidiums, as well as Odontioda Cora, of bright red colour, and Brasso-Cattleya British Queen, of large size and rich colour. Messrs. Charlesworth and Co., Haywards Heath, whose exhibit of new odontonias and odontoglossum hybrids came in for much attention, as also did their Premier type of Odontoglossum crispum. The group of Mr. J. J. Joicey, The Hill, Witley, contained two finely flowered specimens of Cymbidium Devonianum, and among others a large plant of Dendrobium Wardianum.

KELWAY COLOUR BORDERS

The name of Kelway is inseparably connected with the wonderful development of Delphiniums, Pæonies, Pyrethrums, Gaillardias and other Hybrid Plants such as Gladioli. Hardy Herbaceous Plants give a wonderful succession of harmonious tints when grouped together in the **KELWAY COLOUR BORDER,** which can be arranged specially for you. From early Spring to late Autumn your garden may be beautified by groups of colour.

Send us particulars of your border spaces (soil, area, aspect, etc.), and we will make a suitable selection, advising you how to arrange them, or we take your own instructions.

KELWAY & SON *The Royal Horticulturists* LANGPORT, SOMERSET

For success in your Garden USE

THOMSON'S MANURES

On the market for over 50 years, they still hold first place for QUALITY and RESULTS. They are safe, sure and lasting. The direct result of many years' practical experience in gardening, they stand unrivalled at the present day for all Garden Crops.

"They'll be ready in May"

"Oh yes! I know it's weeks earlier than usual. It won't be only potatoes, either—I get *all* my vegetables up early now. I sow them at least a month before I used to, and then protect the sowings with the Chase Continuous Cloche. It makes the very most of every glimmer of sunshine, and gives complete protection from heavy rain and cold snaps, so that the weather doesn't matter a bit. And I get much finer, better-grown crops than I ever did before I started using it."

Made of glass and wire only. Reduces labour of hoeing by keeping surface of ground open. Protects from birds and animals. Free ventilation and absence of shadows ensure sturdy natural growth just as in the open in perfect growing weather.

For general use, order "A" PATTERN, 7 in. high: box of 12, enough for 14 ft., **18/-**; 24, **35/-**; 52, **55/-** For fairly large plants, "B" PATTERN, 9 in. high: set of 15, enough for 22½ ft., **35/-**; 30, **60/-**.

Write for full particulars.

Silver Banksian medals were won by Messrs. Stuart Low and Co., for a group containing the singular Dendrobium linguæforme, and the pretty Cœlogyne cristata var. Lemoniana, as well as Cypripedium Boltonii, with snow-white flowers, and attractive cymbidiums. Messrs. Sutton Bros., Hassocks, Sussex, a new firm, who staged Cattleya Cowaniæ alba, the pleasing Dendrobium Cybele, and a fine example of Brasso-Cattleya Hannibal. A bronze Banksian medal was awarded to Mr. Harry Dixon, Wandsworth Common, for an exhibit of various species and hybrids.

Sir George Holford exhibited a selection of his noted cymbidiums, including Petrel var. Black Dot, in which the lip is blackish crimson and Flamingo, with roundly formed flowers of delicate blush tint. Mr. J. J. Bolton, Claygate, Surrey, staged Odontoglossum ardentissimum var. Robsonæ, with heavily blotched flowers. Mr. F. J. Hanbury, Brockhurst, East Grinstead, exhibited Odontoglossum Porteus, with large flowers of purple colour. Messrs. Black and Flory staged Brasso-Cattleya Mrs. Robert Paterson, of excellent formation and colour, also Cattleya Dr. M. Lacroze, with the lip of intense ruby purple, and C. Tityus, with roundly formed petals.

NEW AND RARE PLANTS.

FIRST-CLASS CERTIFICATES.

RHODODENDRON SINO-GRANDE.—A striking looking species with a large heavy truss of creamy yellow flowers blotched with crimson and enormous leathery leaves, measuring nearly 18ins. in length. Shown by Mr. G. H. Johnstone, Thewithen Probus, Cornwall.

NARCISSUS MEDUSA.—A fine white variety of good form. The flower is of medium size with a slightly reflexed perianth and a cup of bright orange scarlet. Shown by Mr. P. D. Williams, Lanarth, Cornwall.

AWARDS OF MERIT.

AZALEA INDICA ALBERT-ELIZABETH.—Innumerable large semi-double white blooms edged and heavily penciled with clear pink are borne on a plant of good habit and fine foliage. Shown by Messrs. L. R. Russell, Limited, Richmond, Surrey.

CARNATION ROUGE.—An attractive glowing red perpetual carnation of fair size. The blooms are fragrant and carried on long wiry stems. Should prove a good market variety. Shown by Mr. C. Engelmann, Saffron Walden, Essex.

CLEMATIS ARMANDII VAR. APPLE BLOSSOM.—An exceedingly fine clematis, smothered with snowy white blossom, borne in loose axillary cymes. The flowers measure about 2ins. in diameter and the bright green leaves are 4ins. to 5ins. in length and 1½ins. wide. The plant appears to be a vigorous grower. Shown by Captain B. Symons-Jeune, Runnymede House, Old Windsor.

HELLEBORUS ORIENTALIS BLACK KNIGHT.—A very dark variety of this species with purplish black flowers and finely divided bluish-green leaves. Shown by Messrs. Barr and Sun, Covent Garden, London.

LACHENALIA MONTE CARLO.—This Cape cowslip carries, on spikes of 4ins. to 6ins. in length, pendent bells of deep orange shaded with orange scarlet. Shown by Messrs. Carter Page and Co., 53, London Wall.

PRIMULA BAILEYANA.—A dainty Chinese primula with violet blue flowers carried in threes or fours on thin slender stems of 4ins. in height. The small, light green foliage has a deeply serrated edge and the leaf stalks are long and thin. The stems and flowers are lightly dusted with farina. Shown by Lady Aberconway and Hon. Henry McLaren, Bodnant, North Wales.

RHODODENDRON FARGESII.—Pinkish mauve flowers spotted in the throat are loosely carried in trusses of medium size and the foliage is neat and small. Shown by Mr. G. W. Lodge, Wakehurst Place, Ardingly, Sussex.

RHODODENDRON HIS MAJESTY.—A hybrid of glowing rosy red, the trusses are compact and closely set upon the dark green foliage. Shown by Messrs. R. Gill and Son, Falmouth.

SAXIFRAGA ARCO VALLEY.—A member of the Kabschia group, with very pale pink flowers tinged with mauve and neat foliage of glaucous grey. The habit of the plant is good. Shown by Messrs. Clarence Elliott, Stevenage, Sevenoaks.

SOLANDRA GRANDIFLORA.—A showy evergreen shrub, suitable for the warm greenhouse. The flowers are large and funnel-shaped, measuring nearly 6ins. in length. Their colour is creamy white shading to green in the throat. The calyx is long and tubular and the shiny, leathery foliage is most attractive. Shown by The Director, University Botanic Gardens, Cambridge.

SYCOPSIS SINENSIS.—A Chinese evergreen shrub of the Hamamelidacea family. The attraction of this shrub lies in the staminate flowers, which are borne in small heads and carry numerous reddish anthers on slender filaments. The shiny foliage is oval and about 3ins. in length. Shown by Hon. Vicary Gibbs, Aldenham House, Elstree.

ORCHIDS.

ODONTIODA JOICEYI VAR. JOHN COWAN.—An attractive hybrid, which was originally shown with a spike of four flowers by Mr. J. J. Bolton, of Claygate, Surrey, on April 29th, 1924, when it obtained an award of merit. It has now been staged again by the same exhibitor with a spike of nine flowers. The roundly formed segments are of rich crimson colour, except for a narrow white margin, while the whitish lip has a crimson blotch adjoining the yellow crest. First-class certificate.

CYMBIDIUM ALEXANDERI, WESTONBIRT VAR. (EBURNEO-LOWIANUM × INSIGNE).—A first-class certificate wes awarded to this plant on March 14th, 1922, when exhibited by Sir George Holford, K.C.V.O. Since then it has been cultivated to a large specimen, which on the present occasion bore three spikes, with an aggregate of twenty-three large flowers, porcelain-white, the labellum rendered attractive by rosy coloured tracery, while the column is rose pink. It proved the finest orchid of the day, and was deservedly awarded a silver-gilt Lindley medal.

AWARDS OF MERIT.

SOPHRO-LÆLIO-CATTLEYA EDNA VAR. MRS. HANMER.—This remarkable hybrid bore three flowers of a beautiful rose-purple colour, having a crimson tinge and venation of darker colour, the front lobe of the labellum purplish crimson, and the throat veined with gold. Shown by Messrs. J. and A. McBean, Cooksbridge, Sussex.

CYMBIDIUM WHEATEAR, WESTONBIRT VAR.—A distinct hybrid which bore a spike of nine flowers, of yellowish bronze colour, the labellum having a crimson zone of colour on the front lobe. Shown by Lieutenant-Colonel Sir George Holford, Westonbirt, Tetbury, Glos.

CATTLEYA LINDA (COWANIÆ ALBA × LADY VEITCH).—This charming novelty bore flowers of pure white, except for some yellow in the throat, and with the segments prettily frilled at the margin. Shown by Messrs. Cowan and Co., Southgate, N.

CYMBIDIUM LOUISIÆ VAR. SPLENDENS (PAUWELSII × ANDREANUM).—An attractive hybrid of recent origin. The spike carried twenty-one large flowers of light terra-cotta colour, the labellum effectively marked with reddish spots. Shown by Messrs. Cowan and Co., Southgate, N.

CYMBIDIUM TOUCAN.—A pretty hybrid of unrecorded parentage. The spike bore fifteen flowers of reddish bronze tints, the labellum whitish, the front lobe having a crimson band. Shown by Sir George Holford, K.C.V.O.

CYMBIDIUM CASTOR (INSIGNE × WOODHAMSIANUM).—A beautiful hybrid with an arching spike of thirteen large flowers of porcelain white nature, the labellum rendered distinct by rose-coloured markings.—Shown by Mr. J. J. Joicey, The Hill, Witley, Surrey.

A CHOICE SELECTION OF POTATOES AND PEAS

POTATOES revel in a light loam, a soil that crumbles when you touch a clod with fork or spade or crush it in the hand, a soil that is sufficiently retentive of moiture never to become arid—in short, one in which the tubers can develop rapidly. It may be that the reader's garden consists of soil of this nature, but even if it inclines to the sandy side or is of closer texture it will grow potatoes well if a few elementary cultural details are followed out. It is unecessary to enlarge on the advantage of thoroughly digging or forking over the potato plot. Every good gardener knows this. The use of animal manure is also essential. I have often read that the old-fashioned idea of spreading the manure in the rows and planting the tubers on it is the cause of disease in potatoes, and should not be practised. All I can say is that farmers in this district who have grown potatoes all their lives still adopt this method, and they would have ceased to do so if it had not been the right thing. Early varieties are better sprouted. It does not seem to matter whether the sprouts are long or short as long as they are covered over with soil and not allowed to peep above ground before the frosts have disappeared. Regarding artificials to use at planting time, sulphate of ammonia and muriate of potash are generally favoured. Some growers also use superphosphate, but this usually gives better results in the late crops. When earthing up a further light dressing of sulphate of ammonia is sometimes given along the sides of the rows.

EARLY VARIETIES.

There is a good choice of first earlies for garden use, although most of them are not profitable as farm crops. The earliest varieties are Duke of York, Midlothian Early and Sharpe's Victor. The last-named variety is suitable for frame culture, as it has a dwarf habit. Sharpe's Express is a white kidney-shaped variety that usually gives a good crop. Its cooking qualities are probably not first-rate, but when the tubers are sufficiently large for lifting the anticipation of home-grown new potatoes dispels any criticism of quality.

With regard to quality, I know of no finer table potato than Witch Hill, an immune variety. It is a little later than the varieties I have just mentioned, but it soon follows them. The tubers cook

Digitized by Google

like balls of flour, and they retain their quality until autumn, so that the crop can be left to mature and can then be lifted and stored.

SECOND EARLIES.

Great Scot is the popular second early. Its round tubers are large, with eyes of medium depth, and the quality is quite good. I recommend this as a reliable variety for most districts. Eclipse is another favourite, a kidney-shaped, non-immune variety that gives a big crop. The flesh is white and, although it is not regarded as a first-rate cooker, I find that many people like it for the table. Katie Glover gave promise of being a first-class novelty, but I am afraid that it will never give the big crop that the farmer desires—at any rate, not sufficient "ware." However, it is quite a good variety for the garden, and its medium-sized haulm is spreading and gives plenty of cover. I consider this variety the most beautiful when growing, as the foliage is glossy, almost like barberry. Arran Comrade is another good second early for the garden. It is an immune variety with white skin and flesh, and the eyes are very shallow. On heavy soils I have known British Queen, a non-immune white-fleshed sort do well.

MAIN-CROP VARIETIES.

The old favourites, King Edward and Arran Chief, need no comment. Most gardeners know which suits their particular soil. Majestic is a big cropper that is now widely grown. The skin is rather tender, and it will not bear rough handling. This variety should not be too heavily manured or it will grow coarse. The Bishop is one of the prettiest kidney-shaped varieties, and those who like to exhibit could not grow a better maincrop variety. Kerr's Pink, a rather tall grower for general garden use, is a deep-eyed coloured variety that gives a big crop, and its table quality is excellent.

One other maincrop variety need be mentioned, and this for the epicure. It is Golden Wonder, a brown-skinned, shallow-eyed kidney potato with a rich nutty flavour. It will not do well in cold heavy soils, but where it is likely to succeed it is worth growing.

A SUCCESSION OF PEAS.

I usually grow Superb as a first early in preference to Pilot. It is a dwarf, only 2ft. in height, and requiring practically no support; the flavour and cropping quality are both good, and it can be sown very early in the season.

Bedford Champion belongs to the Gradus class, but it is earlier and more robust. It is a heavy cropper with very large pods.

Advance Guard is an immense cropper and the finest flavoured first crop variety that can be grown. It has dark green pods, slightly curved, hanging in pairs and filled to bursting point. I saw a flat of this variety last season that produced one of the heaviest crops known in this district, and the flavour was delicious.

The Cropper is one of Mr. Unwin's best productions, and, like his Advance Guard, gives peas of excellent flavour It grows abot 18ins. high, a little dwarfer than Advance Guard, and is ready about ten days later.

GENERAL CROP.

Chancelot is one of the best varieties that I have grown in this section. It bears a very heavy crop of dark green pods, usually borne in pairs, and it has a fine flavour. The height is about 3½ft.

Rentpayer is a good dwarf variety in this section. It gives a big crop of large-podded peas of quite a good flavour, and may be described as an improved Senator.

One other variety that is well worth a trial is Liberty, a big cropper with large pods hanging in pairs, bearing peas of the finest flavour. It grows to a height of about 5ft.

LATE CROP.

Three varieties will suffice in this section.

The Bell is a very fine late pea with a strong haulm that withstands mildew. The pods are large, in pairs, and of excellent flavour.

Autocrat has the quality of the old variety Ne Plus Ultra, but it is not so tall, only about 3½ft., and it resists mildew well. It is a heavy cropper.

The Gladstone is useful both for exhibition and table, and its handsome dark green pods are borne in pairs.

Sowings of peas may be made from March onwards in almost any locality. The use of too much animal manure produces haulm at the expense of crop. Potash in any form and phosphates should be used, and a constant use of the Dutch hoe between the rows will keep the soil well aerated and also conserve moisture during drought.

NORMAN LAMBERT.

STOPPING AND TRAINING GREENHOUSE PLANTS.

GREENHOUSE plants, whether grown in pots or planted in borders, must be nursed, pinched where shoots are not growing regularly, and trained. Some specimens require to be trained to neat stakes while others must be trained to wires or a trellis. In every case the necessary stopping and training should be commenced while the plants are small, in order to obtain well balanced specimens. Where warm greenhouses exist, coleus plants form lovely specimens when they are well grown. Nearly all kinds of plants have a natural tendency to form one straight stem, and under glass this long straight stem soon becomes ungainly and practically useless. This is not so much the case in regard to the coleus as to many other kinds of plants, as some coleus plants, left to grow naturally, become good specimens, possessing very large leaves. The fine bushy plants, however, are those stopped twice in due course—the central stem once and the resultant side stems once. In the case of fuchsias three or four stoppings may be necessary, and only in cases where certain varieties are pendulous-growing is it necessary to place stakes to the plants. Roses, clematises, passifloras and ivy-leaved pelargoniums, jasminums, hoyas, lapagerias and similar climbing plants should be so trained that their branches will not be overcrowded and thus prevent the natural ripening of the wood. The judicious opening out of the branches of pot-grown plants also helps towards maturity of wood and free-flowering. —CHRISTCHURCH.

FORMING NEW EDGES TO LAWNS: TRIMMING OLD ONES.

A NEAT edge to a lawn, whether it be next to a path or to flower beds, enhances the beauty of the lawn itself. The edge should be a distinct one, but not a noticeable one. For instance, I once entered a villa garden; my visit was to the owner of the house, and did not have any reference to the garden; but I had an opportunity to inspect, briefly, both beds, lawn and paths. The shrubberies were bold and effective, the lawn itself very well kept, but the edges to the beds were 9ins. deep. This defect could have been remedied by raising the soil in the beds to the normal level, as even the soil in the centre of the beds was below the normal level of the lawn. This reference may be helpful to many owners of gardens where the flower beds may be in a similar condition. A too shallow edge is a defective one, too, as it is too indistinct and the lower blade of the edging shears cannot pass under the grass when an attempt is made to cut the latter. It is a good plan to pare off soil from edges now, as all danger of severe frost is past and the soil there will remain firm all through the summer. If severe frost comes after the paring is done the soil edge crumbles away. Where new grass edgings are laid, care must be taken to form a firm, even base of the right depth so that the new turves will be even with the lawn when they are beaten down. The quality of the grass in the new turves should be good, not any coarse tufts of grasses in them. The soil placed under the new turves must not be too rich or the grass will grow much stronger than that on the lawn itself.—HANTS.

MELONS.

THE large leaves of melon plants are arranged alternately on the main stems. From the axils of the petioles are produced the lateral shoots, and these grow rapidly and soon ramble all over if left unpinched. These are the shoots on which the fruits are borne, and they elongate 6ins.—from axil of petiole on main stem—before they unfold a leaf. In the axils and at the base of these secondary leaf petioles are situated the female flowers. It, however, depends somewhat on the variety whether female flowers—later fruits—are sent out from the axils of every first leaf on these primary side shoots, yet as a rule that is where the first female flowers appear on the variety called Ringleader, which, by the way, is a noted variety of many years' standing and, indeed, is still one of the foremost green-fleshed kinds in cultivation. Its encomium for 1926 is as follows: "One of the finest melons. Fruit above the average size, oval in form with a yellow skin beautifully netted over the entire surface. Flesh pale green, extremely thick, with a most delicious flavour. The plant has a robust constitution, sets with great freedom, ripens fruit very early, and does well in frames." Ringleader can be depended upon to bear female flowers—and fruits—in the axils of the first leaf on each lateral shoot. In other words, scarcely a shoot without a fruit. Ringleader is given premier place in these notes, as results have shown that it deserves that honour.

Dover House does not show such a regular arrangement of the female flowers.

Sutton's Scarlet is somewhat similar to Dover House.

Superlative is slightly better than the two former flowers in bearing.—DAVID ARMSTRONG.

GARDEN TECHNIQUE

THE GREENHOUSE

TREATMENT OF OLD ZONAL PELARGONIUMS.

IN hundreds of greenhouses, windows and glazed porches, there are many old zonal pelargoniums, leggy, almost leafless, and certainly neither useful nor ornamental in their condition as described. But it is not at all necessary to discard them. If properly treated they will be both useful and ornamental by midsummer or a little before that time. First take off the tops and insert them as cuttings near the sides of flower-pots filled with a sandy loam made moderately firm. Apply water forthwith, but do not overwater afterwards. Place the cutting pots on a stage or shelf in the greenhouse. The cuttings will be rooted by mid-May. It may be necessary still further to reduce the length of the old stems after severing the tops; if so, the stems may be inserted as cuttings, too. They will be ready for planting out by the middle of June, and will be useful in yielding young shoots in August, available as cuttings to ensure a winter stock. After the old plants have been so cut back, young side shoots will soon grow and when these are 1in. long, re-pot the plants, reducing the ball of soil. Use fibrous loam, leaf-soil, old mortar rubble and a small quantity of bone-meal as a potting compost.—CHRISTCHURCH.

PESTS TROUBLING CHRYSANTHEMUMS NOW.

THE chrysanthemum plant should be grown without any check from the cutting to the flowering stage. Wrong treatment as regards necessary re-pottings always causes a check to growth Wrong treatment as regards ventilation, watering, etc., favours the spread of disease and insect pests. The latter are, mainly, aphides and leaf-maggots; the former, mildew and rust. Usually, ordinary attacks of mildew can be dealt with by a judicious use of flowers of sulphur.

SALE OF ROSES

At 33⅓ per cent. less than catalogue prices.

HAVING so far sold our stock of Roses that the catalogue is no longer a reliable source of selection and not having enough each of different kinds to justify advertising the balance in named collections, we are offering what remains of our stock of bush, standard and climbing Roses in carriage paid quantities in varieties of our selection, at 33⅓ % less than list prices.

The varieties are all first-class (not an obsolete one among them), the trees are excellent and, while all buyers will get remarkably good value for money, the first comers will have the advantage of newer and more expensive varieties for as long as stocks last.

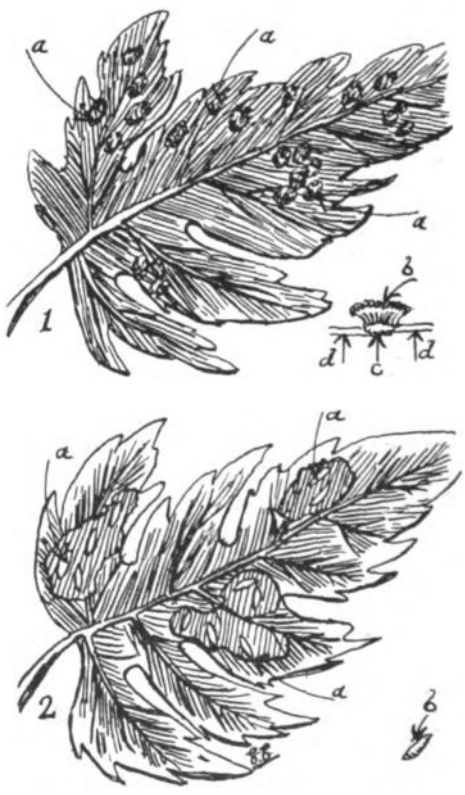
The rust is not eradicated as easily, and many cultivators are having trouble with it this spring. I am showing how it forms on the leaves in the accompanying sketch. No. 1, the underside of the leaf is shown with patches of the rust at *a*, *a*, *a*. At *b* it is also shown, magnified and in section form; it eats away the leaf, forming a hole in it, shown at *c*; *d*, *d*, represents the section of the leaf. Sulphide of potassium in solution will kill the rust. This remedy has previously been recommended in THE GARDEN. No. 2 shows at *a*, *a*, *a*, the leaf-mining grub at work. It is shown slightly magnified at *b*. While the plants are under glass—in a house or frame—it is possible to fumigate them and so destroy the fly. Darlington's Autoshreds will answer the purpose if used twice a week and judiciously. Directly the plants are placed outside scatter fresh soot on the ashes near the plants, also twice weekly till the end of June to render the plants distasteful to the fly. This is more effective



if the leaves are syringed fortnightly with clear soot water. Directly any grubs are seen in the leaves crush them with the fingers. —G. G.

THE FLOWER GARDEN

RE-POTTING WINDOW AND PORCH PLANTS.

THE window or the glass porch serves as a greenhouse to many dwelling-houses. Besides the actual window sills or narrow stages in the porches, small supplementary stages are often erected for the accommodation of pot plants. The latter are raised from seeds, bulbs or cuttings. It is of the latter that I wish to write a few hints now. In thousands of windows the displays of flowers are charming. These good results are obtained by giving close attention to the requirements of the plants in due season. Those that will be benefited by re-potting should be examined now and if, on turning out the balls of soil, roots are plentiful round the sides and in a matted state at the bottom, and, probably, some are perishing, they require re-potting. Those with dead or dying roots should be placed in smaller

Digitized by Google

pots after the old ball of soil has been judiciously reduced. Those possessing many, but healthy, roots, should be re-potted into larger pots. The best general compost for plants, other than ferns, is one made up as follows: fibrous loam, two parts; leaf-soil, one part; sand and old mortar rubble, one part. For ferns, use the loam and leaf-soil in equal proportions and the mortar rubble in place of sand. Provide very sound drainage; do not over water the newly-potted plants; water must not be left in the saucers. For a period of three weeks after the potting remove all flower buds. Sponge and wash large, smooth leaves. Feed the plants later on when they possess many new roots.—CHRISTCHURCH.

MARGUERITES.

A BATCH of marguerites in flower makes a fine display, especially in the winter-time. The shoots should then support sprays of three and four clean, white, yellow-centred flowers. As pot plants they are most useful for house decoration. About the end of March or early in April cuttings should be inserted round the sides of small pots containing fine sandy soil with a modicum of leaf-mould or other opening material. If the plants are wanted to flower in November and December, one stopping will be enough. This should be done as soon as the cuttings are well rooted. Two, three and even four young growths should now spring from each little plant, and if three rooted cuttings are grown on as one plant quite bushy specimens will be had. Two months later plants should be placed in 5in. pots, making the potting mixture fairly firm around the ball of each plant. This is all the repotting the plants will require. Throughout the summer and on till October the plants should be grown in a cold frame, and here they should do splendidly.

The plants after passing out of flower in January should not be cut down. The increased light and warmth of the longer days will encourage the growths at the base of the old flower-stems to push up. Some of the plants at this stage should be set to one side and the young growths when sufficiently matured taken as cuttings. These will produce three and four flower-buds each, so that another display of bloom will be had about the end of March.—D. A.

MISCELLANEOUS

FEEDING ROSES.

BEDDING roses need feeding at this time of the year as well as pruning. After the pruning is finished, food in the form of well decayed manure should be applied. The manure should be very lightly forked into the soil or spread on as a thin dressing after the soil has been lightly turned over. Care should be taken that the roots are not disturbed. Farmyard manure is often difficult to obtain, and has the disadvantage of making the beds look untidy. An excellent substitute for farmyard manure is Wakeley's Hop Manure. This material possesses complete manurial qualities, it is easy to handle, and gives most satisfactory results. A dressing of this kind not only feeds the plants, but also helps to conserve moisture during hot, dry weather. The beds can be made neat and tidy by sprinkling a layer of fine soil over the manure; this hides all the strawy ends.

VENTILATION OF GLASS STRUCTURES AND WATERING IN SPRING

it was cold. As the bright sunshine tempted some inexperienced cultivators to open ventilators wide and so admit the cold air which favoured the increase of aphides, especially on roses, I am giving a few hints here which will be helpful to others during the spring, as we are sure to have spells of hot sunshine and cold winds at the same time. The amateur who, perhaps, possesses a greenhouse or conservatory well filled with flowering and foliage plants, should carefully watch the weather conditions early in the morning, and ventilate accordingly. If the wind is very cold and the sun's rays increase in power, open the top ventilators on the opposite side of the house to that from which the wind blows, if this is possible—just a little at first and judiciously increase the amount of ventilation until noon, but do not admit a lot of air, rather make the atmosphere moister. At the same time, closely examine the pot plants early in the day and again at noon, applying water to those needing it. It is not wise to water plants at this season, late in the day. The sun may make certain plants droop a little, but if the soil is not very dry they will freshen up and not need water before the next day. Extra care should be taken in ventilating vines and peaches, as cold currents of air will cause mildew to spread on young vine leaves and the tiny berries, and aphides, especially black fly on peach shoots. A moist atmosphere on very hot days will be very beneficial in the fruit houses.—GEO. GARNER.

A FRENCH INVENTION—THE RETRO-CULTIVATOR.

MANY gardeners have discovered for themselves the advantage of using a hand hoe fitted with one or two wheels in place of the old-fashioned Dutch or draw hoe, but a French invention, called the Retro-Cultivator, which has been patented in this country, certainly promises to show advantages over any implement of this type we have as yet seen. The inventor had for many years used the type of hoe fitted with wheels which has to be pushed forwards, with the inevitable result that the soil stirred by hoe or plough is again trampled upon by the man pushing the machine. He then thought of a novel and labour-saving method. Why tread on the freshly ploughed soil—why not reverse the tool and pull the machine backwards, using the hands merely to guide the implement? The necessary power to draw the machine through the soil is obtained in a very clever manner. A broad canvas belt is worn by the operator and in front of this belt is fitted a ring, to which the chain of the machine itself is attached. The implement consists of two wooden handles, provided with metal grips for the hands. The handles are joined together at the base by a central bar on either side of which are metal arms containing the holes into which any attachments, such as hoes or ploughs can be fitted and secured by means of a spanner and the necessary bolts and nuts. The arms themselves are adjustable to any angle. In front of the central piece a strong chain is attached and at the end of this is a strong spiral spring fitted with a hook for attaching to the ring on the body belt. Gripping the handles the user walks backwards very slowly, using the handles merely for guiding the implement. About five hundred yards per hour may be covered with a single large plough in use, and up to two thousand yards per hour may be dealt with on light soil when ordinary cultivators are attached and the operator is proficient.

On light, sandy soil near Hampton Court the machine has certainly fulfilled all expectations and the only suggestion that one can make is that winged hand nuts might be fitted so as to do away with the necessity for the use of any spanner.—ROBERT W. ASCROFT.

For Orchards and Fruit Trees.

Nitrate of Soda puts back into the soil what the trees take out—Nitrogen. Helps young trees to grow thrifty and strong; keeps old trees from losing their productiveness.

Read the special pamphlets, entitled "The Manuring of Orchards and Fruit Trees," "Successful Gardens for Every Amateur," supplied gratis and post free by THE CHILEAN NITRATE COMMITTEE, Friars House, New Broad Street, London, E.C. 2.

WAKELEY'S Celebrated Hop Manure

(PATENTED)

THE ORIGINAL AND ONLY RELIABLE SUBSTITUTE FOR STABLE MANURE

AS USED IN THE GARDENS OF GREAT BRITAIN

DIPLOMA AND MEDAL, ROYAL INTERNATIONAL HORTICULTURAL EXHIBITION, 1912

DO YOU REALISE IT?

A large bag of WAKELEY'S PATENTED HOP MANURE at a cost of only 7/- carriage paid to your door (if within 25 miles radius of London, or at a trifling extra if beyond), GOES AS FAR AS A CART-LOAD OF STABLE MANURE, without any of the defects of the latter; gives better results, is easy and clean to use.

Every ounce of Wakeley's Hop Manure is of value to the soil, supplying the necessary HUMUS in addition to the valuable plant food. Worthless rubbish is not added to make weight (as is the case of some artificial manures advertised).

Thousands do realise it, the proof of this is the constant flow of UNSOLICITED LETTERS received from time to time in praise of the wonderful results obtained at such a moderate cost (see Booklet for selection).

BEWARE OF IMITATIONS.—Genuine Only in our Marked Bags containing Guaranteed Analysis.

ILLUSTRATED CATALOGUE giving full particulars and testimonials sent on receipt of post card.

CASH PRICES (including bags):

Small (about 1 bushel)	3/-
Large (about 4 bushels)	7/-
5 Large	33/9
10 Large	65/-
20 Large	120-

Carriage paid by Pickford's or to any station within 25 miles of London, including delivery if within free delivery radius of Railway Company; 6d. per bag extra for every 50 miles or part beyond. Maximum extra charge Great Britain, 2/6 per bag.

GENERAL LIBRARY
UNIV. OF MICH.
APR 7 1926

Vol. XC.—No. 2836 Saturday, March 27th, 1926 Price THREEPENCE

TWO BEAUTIFUL NEW PLANTS

FOR MARCH AND APRIL PLANTING.

MICHAELMAS DAISY BARR'S PINK.
THE FINEST PINK MICHAELMAS DAISY YET RAISED.

Excellent as a cut flower, remaining open and lasting well in water; equally charming in artificial light as in daylight.

"Until lately one had to exercise a certain amount of imagination with the pink Michaelmas Daisies, but now the pinks are really and truly pink, and of the newest varieties none is more prominent than Barr's Pink, which, with great beauty of rich colouring, combines a graceful habit, and one recognises that in this Messrs. Barr & Sons of Covent Garden have raised a variety that will long continue in the front rank of hardy flowers."—COUNTRY LIFE, Oct. 10th, 1925.

Strong plants .. .. .. per doz. **36/-**; each **3/6**

SCHIZOSTYLIS, "Mrs. Hegarty."

(NEW PINK CAFFRE LILY). This beautiful NOVELTY was shown before the Floral Committee of the ROYAL HORTICULTURAL SOCIETY on October 18th, 1921, and was at once given an AWARD OF MERIT. The flowers are of a beautiful satiny rose-pink, and keep on opening out in succession for a very long time. The general habit of growth is that of *S. coccinea*; it is as hardy and requires the same treatment.

A charming pot-plant .. .. per doz. **12/6**; each **1/3**

AUTUMN and WINTER BEAUTY
In the Garden.

WHEN the first Autumn frost has killed the Summer flowers and the last rose is just existing, many people imagine that the garden must be a dull uninteresting place until Spring awakens the early Daffodils.

There are, however, many trees and shrubs which will provide beautiful pictures throughout Autumn and Winter when rightly placed.

What is more beautiful than the setting sun lighting up the berries of the Cotoneasters, Thorns, and other berried shrubs; or the crimson stems of the Scarlet Dogwood, yellow and crimson barked Willows.

We have prepared a short supplement to our general catalogue, giving a list of the best trees and shrubs for Winter beauty, with fuller descriptions and cultural notes. A copy on application. We devote the same care and thought to the cultivation of our immense stocks of FRUIT TREES, ROSES, ALPINES, HARDY PERENNIALS as we do to the SHRUBS.

A Prolific Garden

cannot be maintained without the aid of some kind of manure. Stable manure is now scarce, and is bulky to cart and spread on the land. No artificial will altogether take the place of natural manure, but a good well-balanced fertiliser, used during the growing season, is a wonderful aid in producing high-class garden crops. No fertiliser is cleaner, more effective, or economical than

PEARSON'S CHEMICAL MANURE

which is compounded from the purest chemicals. It contains every element necessary to plant life which is not present in any ordinary garden soil. A glance at the analysis will prove that this manure is as cheap as any on the market, while nothing can beat it in ease of application and results.

ANALYSIS
PEARSON'S "CHEMICAL MANURE"
(ARTIFICIALLY COMPOUNDED)
Contains at least 11·79 *Phosphates, soluble and insoluble;* 6·68 *Potash;* 6·44 *Nitrogen* (*Ammonia Nitrogen* 4·56, *Nitric* 1·88).

Per cwt. 25/-, ½ cwt. 13/- carr. paid. ¼ cwt. 7/-, 14 lb. 4/6, 7 lb. 2/9, carr. forward.

AN ANSWER

A CONTRIBUTOR to this week's issue has answered an article which I wrote last year on hybridising. I can refer those who are interested to "Where will it End," published May 16th, 1925. In his reply "L. R." has misunderstood the object of my previous article. I did not decry hybrid rhododendrons as such, but I did try to warn enthusiasts against indiscriminate hybridising. I frankly agree that hybrids flower better and at a younger stage than most species; I also admit that for ordinary gardens where space is often at a premium a quick and certain flowering hybrid is better than a slow-growing and doubtful-flowering species. What I have to complain of is that "L. R." and other enthusiasts blithely cross each new rhododendron as it flowers with everything in sight in their own garden and with what they have heard of in their friend's gardens, searching blindly for a better plant. If they confined themselves to trying to fill gaps or to better some individual plants, I should have no grounds for complaint, but these enthusiasts are nothing if not lavish in the scale in which they produce new seedlings, and I think that my remark "Where will it end?" is justified. Perhaps in their enthusiasm amateur hybridists forget that every hybrid seedling is different, and also the time that it takes for a plant raised by an amateur to get into general cultivation. Let us take "L. R.'s" own figure of flowering in seven years from seed. There are only three methods of increasing a hybrid—cuttings, layers and grafts. Remember that one plant only of a particularly fine form may be raised from seed. It is unlikely that the raiser in his first enthusiasm will denude or throw the entire plant for the benefit of others. Perhaps three or four cuttings or layers may be taken from it in the first two years; these have to grow for a year or two before they can be propagated again. In fact, I doubt if a fine hybrid can be reproduced in large quantities in under thirty years. No one can expect the amateur raiser to be so altruistic as to ensure other people's enjoyment of a plant he has raised before his own.

This argument may appear shortsighted, but it, naturally, only applies to the present generation, in which I happen to be interested. Doubtless the sheep will be separated from the goats by the time the next generation is old enough to appreciate rhododendrons, but the results of the frenzied hybridising that has taken place since the war will have no general influence for many years to come. There is a great deal to be said for older hybrids, for they were made at a time when the majority of species in this country were not satisfactory garden plants. Hybridists, such as the Waterers, Mr. Mangles, Cunningham and Fraser, Fisher Sons and Sibray and Sir Edmund Loder, set out to fill a gap and set about it on definite lines with admirable results. It is doubtful if more floriferous plants than Loder's White, Manglesi, Duchess of Portland, Cunningham's White or Pink Pearl could be found.

It must also be remembered that new hybrids must differ absolutely in some definite point, such as date of flowering, infinite superiority of colour and shape, and so on. It is easy for the specialist to make comparisons when he has every variety growing in his garden, in addition to a perception trained by long years in growing rhododendrons. It is much more difficult to persuade the tyro who has admired, say, three species or hybrids in a friend's garden and can perhaps only recognise ten or a dozen kinds that a novelty is better than an old form. He has few means of comparison. This, of course, applies equally to new species.

Keen as I am on rhododendrons, I realise that the enthusiast is in a fair way to defeating his own ends by the multiplicity of species and hybrids. The beginner can hardly see the wood for the trees. Doubtless there are many species and hybrids which will be so infinitely better than their neighbours that they will tower as giants out of the wood, but in the present state of flux the beginner, however much he may admire rhododendrons, will stick in desperation to those plants which he knows. And he will probably be right.

Yet in a way this is a pity, for there are a number of good new species and a few new hybrids that have already appeared that are worthy of much more notice by the amateur beginner than is paid them at the present. I shall give just one instance, some of the rhododendron species that centre round R. triflorum. They are as floriferous as most hybrids; they are easy to grow and take kindly to most positions provided that they are not in full sun. I mean such rhododendrons as Augustinii, yunnanense, chartophyllum, villosum, ambiguum.

E. H. M. C.

AMONG THE ARTICLES IN OUR NEXT ISSUE WILL BE:

CAPRICIOUS PLANTS, by Flora Dysart.

SHRUBBY VERONICAS, by C. M. Bailey.

THE MAKING OF A WATER LILY POND, by A. Osborn.

The front cover of our Spring Number, which has been so much admired, is an illustration of Messrs. Carters' Wallflowers.

A RHODODENDRON TOUR in SIKKIM

IN May of last year, under the guidance of a friend who has an intimate knowledge of the district and its flora, I spent a fortnight among the rhododendrons in Sikkim. A few notes on what I saw may possibly be of interest to rhododendron lovers.

The setting is very grand. In the lower altitudes semi-tropical trees of superb proportions; higher up, steep mountain slopes in sweeps of 5,000ft. to 8,000ft.; and, over all, the 28,000ft. snows. Seldom, however, could all this grandeur be seen, for the flowering time of the rhododendrons coincides with the season of mist and rain, and sometimes for days together, we passed through what we knew to be some of the finest scenery in the world, seeing nothing beyond the immediate foreground save an infinity of mist. The too frequent absence of sunlight made efforts to photograph both difficult and unsatisfactory, and many a fine subject had to be passed by unrecorded.

My first rhododendron was R. Dalhousiæ, and it was indeed a thrill to find this greenhouse treasure growing profusely in the little rocky glens which opened off the roadway, and even by the roadside itself. It also frequently grew high up on the trees as an epiphyte. Next came R. Edgeworthii, a whole hillside of it, filling the air with its fragrance. These were near Darjeeling. It was not till we had reached 10,000ft. to 12,000ft. altitude towards the frontier of Nepal that we got to the true rhododendron area. *Trees* of R. Falconeri, 20ft. to 30ft. high, laden with great trusses of blossom; R. arboreum still bigger; R. cinnabarinum var. Roylei; R. fulgens; miles of R. campanulatum, and miles of R. Hodgsonii. Lower down we found two plants—the only two in our tour—of R. Aucklandii, which does not seem to be common, in this district at any rate.

For the most part the different species were rather segregated, but sometimes they mixed. One hillside was specially memorable. For a background there was a subtle mixture of grey greens, russet and purple browns, and the very dark green of conifers. Interspersed were the rhododendrons, ranging in colour from sulphur, through apricot, salmon, greyish peach, pink and rose red, to deep crimson, with here and there a little mauve or lavender, the whole suggestive of the soft richness of a splendid tapestry.

Crossing Sikkim eastwards we sank below the rhododendron region, and it was only on approaching the Tibet and Bhutan frontier—10,000ft. to 13,500ft.—that we regained it. Here again were nearly all the varieties we had found in the west, with some notable additions, such as R. cinnabarinum var. blandfordiæflorum in its ordinary form, and one plant of it of a scarlet of the intensity of Lonicera fuchsioides, and, like that honeysuckle, with a narrow edging of yellow to its waxy bells. Here were the largest plants of R. cinnabarinum var. Roylei and R. Thomsonii that I have ever seen, reaching 20ft. and over, and a mass of gorgeous crimson blossom. Also R. campylocarpum, and, to my surprise and delight, numbers of a natural hybrid between R. campylocarpum and R. Thomsonii, ranging in colour from the sulphur of the one, through apricot and salmon, to the crimson of the other. The shape of the corolla was like that of the parent plants, and the calyx about half-way between the inconspicuous one of R. campylocarpum and the large one of R. Thomsonii.

R. WIGHTII WITH THE WHITE FORM OF R. CAMPYLOCARPUM IN THE CENTRE.

I had the good fortune to find a white form of R. campylocarpum, only one plant among the thousands I saw. It was of great beauty, the bell having a shade of ivory in its depth, and a sprinkling of claret-coloured spots in the middle upper segment.

Getting to about 12,000ft. we attained one of our chief objectives, the region of R. Wightii—miles and miles of hillsides covered with it. Here again I had extraordinary good fortune, for of this also I found a white form. Though not of the largest size, nor possessing the globular truss of the best forms of R. Wightii, it was very beautiful. The blossoms had a faint suspicion of mauve in the bud state, and were thickly spotted with claret red in the upper part. The leaves were less brown on their under sides than are those of the normal form. Though I saw I suppose hundreds of thousands of plants of R. Wightii, I found but one white one. In fact, I am informed that it has not been recorded before. I may here mention that our fires—very necessary at these cold heights—were built of faggots of R. Wightii wood!

One point which struck me forcibly was the great difference in horticultural value which exists between the different forms of some of the species. This is especially true of R. Wightii. One would hardly want to grow it in its poorest form, with loose truss and smallish bells, whereas in its finest forms I would count it one of the noblest of the genus. There are two of these very fine forms. Both have large leaves with rich brown under sides, and large globular trusses of flowers of soft, pure yellow and solid texture. In one variety the centre of the upper part of the corolla is heavily spotted with claret red; in the other a blotch of the claret red occupies the base of the bell, the rest of which is self-yellow.

Of R. Dalhousiæ there were two forms. One had rather smaller flowers of a slightly deeper shade of yellow than the other, which was larger and finer, and went to palest ivory white when fully expanded.

There was another rhododendron resembling R. Dalhousiæ, but which was white with a faint flush of pink on the outside and a yellowish stain in the bottom of the bell, and exceedingly sweetly scented. It was suggested to me that this also was

R. EDGEWORTHII ON THE HILLSIDE.

Digitized by Google

R. Dalhousiæ; but I thought it could not be, for I had never seen that rhododendron with any trace of pink in it; as I know it, it goes from green in the bud through greenish yellow, yellowish to ivory white in the full blown flower. On my return home I found that Hooker in his "Rhododendrons of the Sikkim Himalaya," describing the blossom of R. Dalhousiæ, says: "Corolla white . . . with an occasional tinge of rose. In age the flowers assume a delicate roseate tinge." I have been endeavouring to find out if this pinkish form of R. Dalhousiæ is known in cultivation, but so far without success. It would be interesting to learn if any of your readers know of it—a *true* R. Dalhousiæ, not a hybrid form. If such a plant is not known I would—if one so ignorant of botany as I am might venture to do so—hazard the suggestion that when Hooker spoke of R. Dalhousiæ as having flowers sometimes tinged with rose, it was R. Lindleyi, not R. Dalhousiæ that was in his mind. Mr. J. Hutchinson points out ("Notes from the Royal Botanic Garden, Edinburgh," Vol. XII, No. LVI) that both in Hooker's dried material of R. Dalhousiæ and in the coloured plate of it there are portions of R. Lindleyi (which was not distinguished as a separate species till many years later) mixed up with it. If, then, Hooker mixed the plants, it is possible that he mixed the colours of their flowers also, and that would account for his statement that the flowers of R. Dalhousiæ are sometimes tinged with rose, which surely is not characteristic of them as generally known in cultivation.

But to return from this digression. Most of the plants of this last-mentioned rhododendron were epiphytes growing so far up the trees that their presence was made known only by the fallen bells strewing the ground below.

R. campanulatum ranges from a delicate lavender to an unpleasant purple. Some forms of R. Hodgsonii are of a beautiful peach pink, while in the normal form the pink has too much of blue in it to be quite pleasing. Of R. campylocarpum there is a small form as well as the larger and more desirable one. R. arboreum varies very greatly both as regards form and colour. I may say that I did not find any plant of it as fine as the blood-red one in the Temperate House at Kew. R. Falconeri occurred both with and without the purple spot at the base of the bell, and R. Thomsonii varied greatly both in the size of the blossoms and in the depth and purity of their colours. What one would like to do would be to make this tour in spring, marking the finest forms; then go over it again in autumn, gathering seeds from or digging up seedlings from under these marked plants.

After the rhododendrons, the plants which interested me most were, I think, the arisæmas, of which there were many strange and beautiful species. The most wonderful was A. Wallichianum, with its very large frilled and ribbed greenish and purplish marbled flower, lined with velvety chocolate purple, and having its spadix terminating in a thread 18ins. to 21ins. in length, which gets entangled in the neighbouring leaves. I can only suppose that this threadlike appendage must be meant to form a path along which small insects may be led to the pollen, and so effect pollination and ultimately fertilisation.

Besides these, there were innumerable other flowers of the greatest beauty and interest, ranging from orchids, hoyas and such-like tropical plants in the valleys, up to primulas and alpines on the heights.

Altogether this visit to Sikkim is a never-to-be-forgotten experience, and is a help to the better appreciation of the achievements of the plant-hunters of the remoter east. J. C. W.

[Since the above article was written the dried material of the white form of R. Wightii has been examined by Professor Wright Smith, who confirms an additional distinction between this form and the type, namely, that the form exhibits an almost glabrous ovary and might be provisionally named R. Wightii var. leucochroum.—ED.]

TYPICAL RHODODENDRON COUNTRY AT 13,500 ft. WITH A WHITE FORM OF R. WIGHTII IN FOREGROUND.

ON HYBRID RHODODENDRONS

SOME time last year an article appeared in THE GARDEN decrying the hybrid rhododendron. I am aware that it is the fashion to state that the species is so much more refined, and I agree that no more glorious sight is possible than a large Aucklandii in full bloom in a Cornish garden, or even an Augustinii or a campylocarpum in some of the less favoured districts of England; but, generally speaking, it is from the hybrid rhododendrons and azaleas that the majority of gardens derive their great annual colour treat. The Waterer and the Dutch hybrid rhododendrons flower year after year with unfailing regularity wherever they may be planted, so long as the soil is free from lime. With the species, however, the vagaries of our British climate have a great deal to say as to the effect that we shall get in our gardens; should, in any particular year, they happen to coincide with those of the locality where a particular plant grows wild, it might be good, but this is not always so. Some years may be too dry, some too hot, some too mild in the winter and some too cold—one year it may be the early autumn frost which blackens the buds before they are hard and well set, at other times it is an early spring frost which catches them just as they are coming into flower. It stands to reason that all these species which have been introduced from different altitudes, different latitudes and, above all, coming from places where the rainfall varies from 24oins. a year in some cases to 30ins. to 40ins. a year in others, cannot all find our climate to their liking; the hybridist on the other hand has evolved a race eminently suitable to our part of the world.

It is true that in some favoured gardens the trusses may be larger, the colours more intense; but, generally speaking, Cynthia or Pink Pearl, Britannia or Doncaster, Helen Schiffner

Digitized by Google

or the Duchess of Portland can be depended upon to give, year in and year out, a blaze of colour for the few weeks during which these plants are in bloom. These rhododendrons are all raised with the aid only of the Himalayan rhododendrons introduced by Hooker and the addition of catawbiense and ponticum.

With the entry of the new Chinese rhododendrons a much greater chance for the skilled hybridist has arisen. By using iscolor and auriculatum, we have a chance of prolonging the season until June or July, and we may perhaps be able to produce late hardy rhododendrons of as beautiful a hue and shape as those Aucklandii and blood red arboreum hybrids which now can only be grown in the milder gardens on our sea coast. How many people have admired the exhibits that Gill has put up at the Royal Horticultural Hall in the early months of the year and wished that they could grow those plants in their gardens. With successful hybridising, this should not be impossible.

DUCHESS OF PORTLAND ONE OF THE BEST WHITE HYBRIDS

Take only two of the newer Chinese rhododendrons which have been introduced as examples of what might be done. Few will deny that any more startling colour has ever been seen in a rhododendron than that of Griersonianum, and many may say that no more beautiful shrub could be evolved by the hybridist, and yet in many gardens at present this forms a loose-growing bush—free-flowering, it is true, but never sufficient to stand out in the landscape. This may be due to the fact that no mature bush is yet to be found in a British garden; but it hybridises very freely, and surely this must help to improve the colour of our garden hybrids—a compact, free-flowering bush with a good truss and the glorious colour of Griersonianum would surely be a very desirable asset to British gardens.

The neriiflorum section also is one which may help to produce many small, brilliant-coloured hybrids for our gardens. Neriiflorum itself flowers very freely, and when seen at its best in Cornish gardens is a glorious blotch of scarlet on the landscape. The hæmatodes section, which has larger flowers, only occasionally flowers freely—perhaps, again, because the plants are not large enough at the present time; but hæmatodes will often miss a year's flowering, and with successful crossing there is no doubt that this section will give a series of compact dwarf rhododendrons, which will flower every year and will grow in every garden.

Life, unfortunately, is very fleeting: the writer has watched rhododendrons growing year after year, hoping some time to see a flower bud form; year after year the species have grown bigger and bigger, full of vigour and health, pleasing in leaf, but with no sign of bud. Some of these tree rhododendrons take twenty to thirty years to flower, and then only flower really well once in every three years—in fact, the owner of one of the finest gardens in Cornwall stated only the other day that he had only seen once in thirty years a large plant of Falconeri really covered with bloom in his garden.

Hybrids usually start flowering after seven years and, once they have started flowering, are fairly consistent; and as the whole object of a garden is to beautify nature with colour, it seems to the writer that it is the hybrid rhododendron which will appeal most to the majority of garden lovers in this country and that the real use of all the explorations into the Roof of the World for new plants is to give the curious plants to collect, and the hybridist scope to fill the gardens of Britain with beautiful shrubs and plants.

L. R.

RHODODENDRONS IN WIND AND DROUGHT

IN the introduction to his invaluable book on rhododendrons Mr. Cox suggests mass planting of the moorland species in open windswept ground in place of heather. I have not yet enough plants to carry out mass planting, but I have a scrap of moorland windswept enough to afford as severe a test as anyone could wish for, and though the planting is as yet very young, it is old enough to have afforded already some striking indications of the power of these mountain rhododendrons to withstand extremes of wind and of drought.

The garden is over 600ft. above the sea, on open moorland so sheared by the Atlantic winds that for some miles around not a single tree exists, except a few down in the vicinity garden and at one farm. There is hardly a tree between here and Land's End, hardly a bush taller than gorse. The garden includes at its highest part, a bit of moorland, from which I have cleared couch grass and bramble, leaving nothing but clean native peat and rotted couch-grass and the beautiful fern-clad granite rocks. RR. oleifolium and racemosum were among the first to be tried, and these have not turned a hair, even in the most ferocious gales. They have flowered very freely and are making excellent growth. R. hippophæoides, also, planted closely, in damp, rather stony soil, is very happy, and so, rather to my surprise, is R. primulinum, though this has not yet flowered. R. cuneatum appears to be equipped for my trials. Its leaf has a satisfactory toughness, and as the plant comes from southward-facing cliffs, I am going to try it in some quite shallow soil on the rock. Sphæranthum and ledoides share the same conditions as hippophæoides and get some shade from a young pine. I think these will go on all right, though I do not feel quite so sure about them as about the others. Sphæranthum was a lovely sight when it was out last May, with its flower-heads like rosy white daphnes, and the aromatic scent is alone sufficient inducement for one to make every effort to grow this delightful plant. Myrtilloides, calostrotum and impeditum grow together on top of a rock beside the path. The soil is very shallow, and they had to face seven weeks of unbroken drought last summer, but with the help of a mulch of lawn

Digitized by Google

mowings they pulled through perfectly when Erica vagans near by was actually killed. Each plant has about doubled its size in a season. The little mounds of myrtilloides, with crimson-brown varnished leaves and the whitest of glaucous leaf-buds, are certainly very attractive; and calostrotum, I am glad to find, is as easy to strike from cuttings as I had hoped. Caloxanthum, with pale yellow bells, has not flowered yet, but is doing well. I hope the six or seven plants will grow together presently and make a thicket such as Farrer describes. Sperabile, which is reputed to be difficult, is doing well so far, though not yet of flowering size. I tried to imitate for these the mossy scree Farrer mentions as their home. They get so much wind that most shrubs so situated would lose all their leaves in the first gale. Dichroanthum is another stout fellow, hard as nails it seems. I wish I could mass this, as Mr. Cox suggests. And I believe aemulorum is going to prove one of the toughest of all. The leaves of this have a leather strength, so that, Farrer said, it can hold aloft its heads of blazing crimson-scarlet flowers in the storms of snow and sleet on the mountains of its home. I hope I shall see these little plants turn into trees with gnarled grey trunks.

I had supposed that citriniflorum and sanguineum would stand the same sort of conditions as sperabile, for they come from screes and among boulders high on the mountains, but the attachments of their leaves seem to be too fragile. Sanguineum has not liked the ordeal a bit, though some plants of citriniflorum are coming through all right.

Rubiginosum, the triflorum series, and plants such as searsiæ and zaleucum get cut to bits in such an exposure as I have been speaking of, though I am hopeful that oreotrephes may prove able to stand it. I think hæmatodes will be all right, but have not yet given it the full dose of wind. Moupinense, which will certainly stand exposure in mass planting, flowers so early and is so beautiful that I have not yet put it in quite so wild a place, and the same applies to ciliatum.

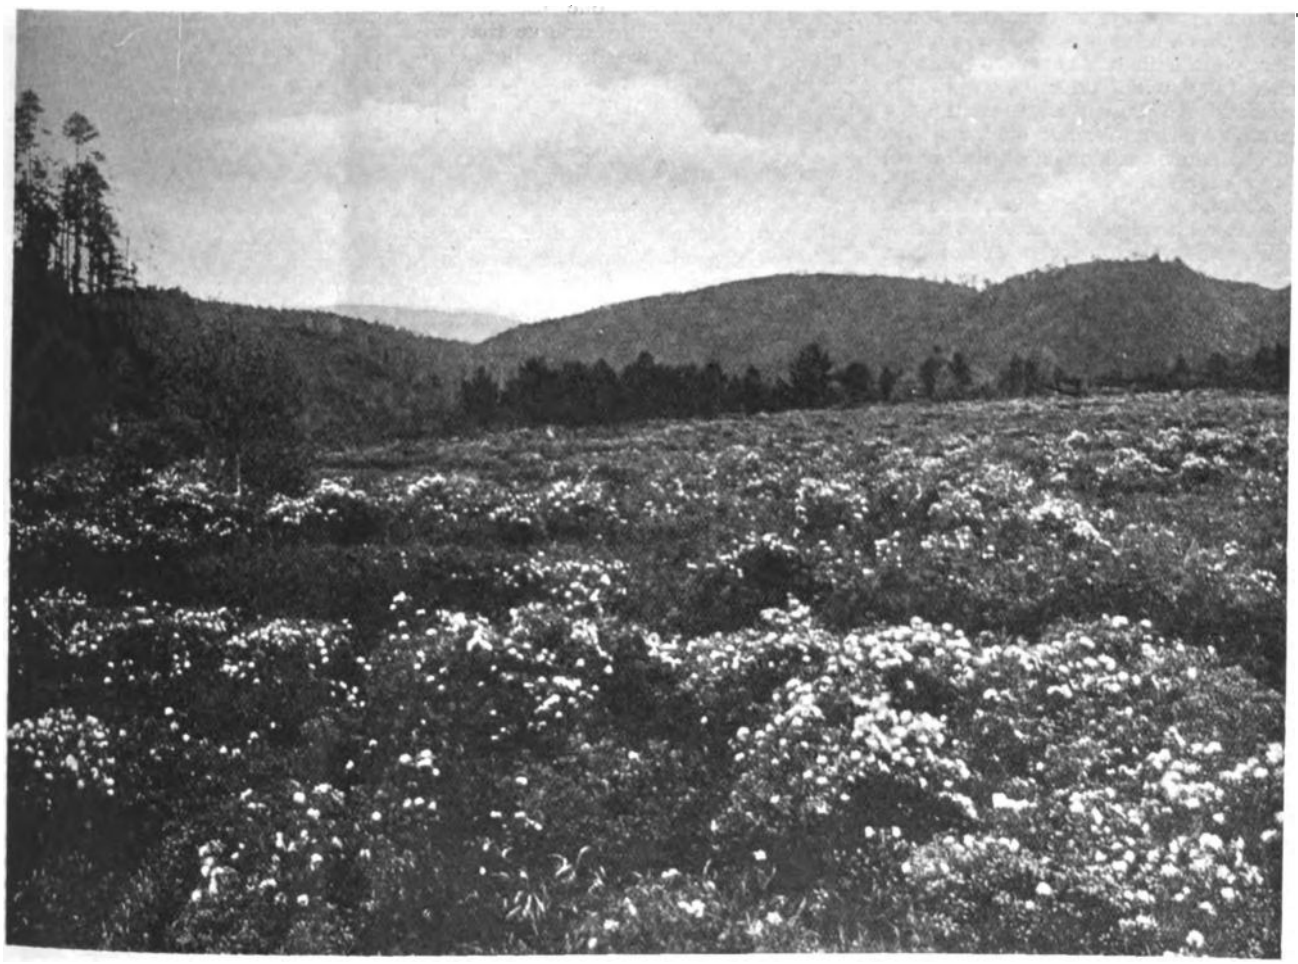
There are hundreds more species worth trying, if these will do. Megeratum, for instance, in yellow, and aiolosalpinx in white to crimson, and scyphocalyx in some coppery colour, martinianum, plebeium, troops of them that I have not tried. But these beginner's notes, based though they are on all too brief and narrow an experience, may perhaps serve to cheer some other experimenter in some other windswept garden. Perhaps, if I am lucky, they may lead some expert to be so kind as to advise me. Mr. Tagg recently pointed out in these columns that many of the mountain species are xerophytes, able to stand extremes of drought. Mr. A. Olsen, writing from Denmark, has shown that many can stand extremes of cold, and as regards those species I have named (and presumably many more), a similar claim can evidently be made as regards resistance to wind. W. ARNOLD FORSTER.

P.S.—In order to test these statements further I have held up this article till we have had some more first-class winter gales, but all the plants have passed the test.—W. A. F.

THE RHODODENDRON BUG*

BY J. C. F. FRYER

IN an issue of this journal devoted specially to the rhododendron, so important a pest as the rhododendron bug could hardly be overlooked; but it must be admitted that there is yet relatively little to add to articles on the subject by Mr. Hoare and Mr. Fox-Wilson which have appeared in the Journals of the Royal Horticultural Society (Vol. 48, page 16, and Vol. 50, page 46). The following notes must, therefore, comprise much which is already



RHODODENDRON MOORLAND IN CHINA WHICH MIGHT BE COPIED TO ADVANTAGE IN THIS COUNTRY.

* Leptobursa rhododendri, *Hartwig*.

Digitized by Google

well known to rhododendron growers, but it is hoped that they may, nevertheless, prove of some interest by drawing attention to various considerations of a practical character in connection with the control of the bug.

The rhododendron bug—sometimes, though incorrectly, called the rhododendron fly—is a foreign insect, probably of American origin, which obtained entry into this country some time prior to 1910. It may have arrived on rhododendrons from Holland, where it had been detected as early as 1908; or it may have come direct from the U.S.A., where it has been found upon wild plants of Kalmia latifolia and Rhododendron maximum. However this may be, by 1913 the pest was well established in Surrey and probably in the adjoining counties of Hampshire and Sussex, where it was detected shortly afterwards. It succeeded in establishing itself unobtrusively and without attracting the attention of rhododendron growers until it had already spread too widely to justify attempts to bring about its complete extermination.

Here the first practical point emerges. There are, probably, in the wilder countries in which rhododendrons are native, other pests still unknown to science, which may work their way towards England. At present there is in force legislation which did not exist in 1910 and which now tends to check the arrival of foreign pests. If such pests are detected soon after their arrival, it should prove a relatively easy matter to exterminate the first colonies; once, however, a pest is well established, it usually proves quite impossible to eradicate it, and the most that can then be sought is an efficient means of control. The co-operation of rhododendron growers (particularly of those who import plants from abroad) in the early detection of new pests is, therefore, very desirable.

HABITS OF THE PEST.

The insect is in the egg stage during late winter, the eggs being inserted well inside the tissues of the midribs on their undersides, rarely in other parts of the leaf, the position of each egg being indicated by a small scab of gummy secretion. So far as is known, the bugs do not lay their eggs in any other part of the plant, such as the stem or buds, as has been suggested. It, therefore, follows that, if the leaves of an infested bush are removed in winter, the bugs will be destroyed—a fact confirmed by an experiment in which bushes, heavily infested and showing large numbers of eggs, had all their leaves removed two or three years ago and have remained quite free from the bug since.

During the last days of May and practically throughout June, the young bugs are hatched from the eggs and at once begin to suck the sap from the undersides of the leaves, causing the familiar signs of damage. The length of the hatching period is of some practical importance and may have led to failures in spraying, owing to the work being done before the hatch was completed.

By about the first week in July the earlier hatched bugs have become adult and have obtained the beautiful lace-like wings which are so characteristic of them: the remainder arrive at maturity as the month proceeds. Eggs are laid in July or August; gradually the bugs die, and no more will be seen until the following year.

A last practical point in connection with the insect's habits concerns the use of its wings. No one appears ever to have caught the bug flying: it is possible it does not fly, in which case a garden once freed from the pest should remain free until infested plants are again introduced. But there is also the fact that very sluggish winged insects occasionally require exactly the right weather conditions before flying, and it may be that the rhododendron bug only flies on very occasional suitable days. The possibility is worth investigation by anyone situated in a district where the bug is plentiful, for it has a definite bearing upon the selection of control measures.

NATURAL ENEMIES.

When a foreign insect becomes established in a country, one of the first measures to take is to arrange that the pest's natural enemies—ichneumon, chalcid and tachinid flies, etc., should follow it. Unfortunately, no such enemies of the rhododendron bug are yet known, and until they are discovered this measure cannot be taken.

CONTROL MEASURES.

In the American *Journal of Economic Entomology* (Vol. VIII, page 409–414), Crosby and Hadley write as follows: "Our experience has shown that it is not a difficult matter to control these insects. They may be killed by a soap and water spray at the rate of 1lb. soap to 10 gallons water." (U.S. gallons.) Mr. Hoare's experiments, as well as those of others, confirm this statement and prove that the bugs are readily killed either by a soap spray (soft soap 1lb., soft water 10 gallons) or a nicotine and soap spray (soft soap ½lb., nicotine 95 per cent. ¾oz., soft water 10 gallons)—indeed, they are very susceptible to the action of any contact insecticide, as they are incapable of moving rapidly away from its influence. Nevertheless, it appears that, in practice, difficulties have been found in controlling the bug by spraying, and it is of importance to discover the cause of these failures, since spraying is almost the only weapon available for use against the bugs. Reference has already been made to too early spraying as one possible source of failure. The converse is also true—if the spray be applied too late, *i.e.*, after some bugs have become mature and laid eggs, the result would also appear good, but the following year the bushes would again be found to be infested. Where they can be afforded, perhaps two sprays will be found best, one about the middle of June and the second about July 8th.

Another difficulty is likely to be encountered from the fact that the bugs live on the undersides of the leaves and that rhododendron bushes—at all events, of some varieties—are very dense, so that it is not easy to spray in such a manner as to reach all the insects. This source of trouble can only be overcome by efficient work and efficient tackle, and as the spread of the bug from bush to bush is slow, it would probably pay to deal with any considerable area of rhododendrons by spraying each year only so large a block as can be very thoroughly treated.

In connection with spraying, it may be mentioned that it is just possible that dry spraying with a nicotine dust might prove useful, as dusts will often work their way into corners which a wet spray will not reach; but experiments with dusts do not appear to have been recorded.

Finally, there is a third difficulty in dealing with the bug in those areas in which rhododendrons of miscellaneous varieties have been planted in woodland and under semi-wild conditions, so that thorough spraying is not feasible. Here there appears to be no remedy, unless it should prove possible to prune back the bushes between autumn and spring in such a way as to remove their leaves, dealing with the area in small blocks. It remains to rhododendron growers to say whether this is anything more than a wild suggestion. The few bushes which were mentioned previously as having been defoliated in winter appeared to suffer no permanent injury from their treatment.

Finally, it may be emphasised that the two dominant factors in the control of the pest are, first, the ease with which it is killed when *touched* by an insecticide; and, secondly, its sluggish nature, which should permit any treatment to be carried out gradually, dealing each year only with the number of bushes which can be thoroughly sprayed.

SPRING FROSTS

GARDENERS know only too well the immense amount of damage which is done, particularly to fruit trees, by spring frosts. Quite often the giving of a little protection to a particular tree may be the means of saving a fruit crop. In the case of a large tree it is difficult to do much, but with smaller specimens, and these trained on walls, a few pieces of sacking, or even paper, will check the worst effects of the freezing temperature. It is well to bear in mind the conditions when a frost at night in the spring months may be expected. In April it is not uncommon to experience a spell of wintry weather. The wind is in a northerly quarter, and, if the barometer falls, there is every probability of hail or snow showers, followed by frost of some severity. Again, in the same month, during a spell of rainy weather when the wind is in the south or south-west, the glass falls and the wind veers to the north or north-west. Often this change comes in the late afternoon, and then the sky clears and there is a rapid drop in temperature. Another type of weather during which frost may be expected is that which often occurs for some weeks in late March, April and even May. Here the days are fine and bright and, under the influence of the sun, temperature may be relatively high. Owing to the clear sky the thermometer falls quickly after sundown, and very sharp frosts will ensue. At such times the difference between the highest temperature of the day and night will be very considerable. Naturally, this warming and chilling is likely to do harm to many kinds of vegetation. S. L. B.

FRAGRANCE IN HERBS, ALPINES AND WATER PLANTS

I CAN imagine no more delightful method of approaching the kitchen garden than along a pathway composed of red bricks, fringed by a broad band of white pinks and enclosed upon both sides by an old but well kept lavender hedge. Let the actual entry be framed in an arch of honeysuckle or fragrant roses and, so that the transition may be gradual; mass fragrant herbs in beds and borders immediately within the entry.

Take rosemary, for instance. Would you forego its fragrant charm? Certainly not, and a great spreading bush or two forms a delightful welcome. If wished, this may, by trimming, be induced to form a low hedge, a fitting continuation of the lavender walk. All sorts and conditions of herbs should fill up the borders, not forgetting the annuals—such as sweet basil—as well as those of more permanent duration. Here, a mass of hyssop; there, a clump of grey-green sage, rubbing shoulders with thyme and balm and marjoram; while height is secured by the addition of a few plants of fennel, with its sturdy growth and finely divided leaves.

ALPINES.

Let us now journey to the rock garden and see what may be found in the way of fragrance. Nothing in this part of the garden excels the dianthus for perfume and also variety of colour and form. There are, indeed, dianthus and alpine pinks that will fit in with every conceivable condition that may be encountered, whether this be soil or position and whether a close, compact clump or a broad spreading mass is the desire. One of the commonest plants that is particularly good for shaded corners where it can be allowed to run semi-wild is Asperula odorata. In spite of the ease with which this may be grown and the rapidity with which it spreads, it is really a very choice plant when seen at its best, with the deep green whorls of leaves surrounding the stems and every point tipped with a beautiful cluster of starry white fragrant flowers. Flowering simultaneously with the forget-me-not and interplanted with a deep blue variety of this, one plant sets off the other and a delightfully delicate colour picture is produced.

The violet is another plant for the alpine garden, and we would put in a plea for it in its simplest form. By this, we mean that the finest doubles or the giant singles should not be chosen, but just the small purple or white fragrant forms. Another simple flower with a distinctive fragrance is the cowslip, and it should not be forgotten that this may now be obtained in a variety of garden forms, the curious little flowers appearing in nearly as wide a colour range as the polyanthus. Silvery leaved shrubs are always valuable in the rock garden, and one beautiful example of this is to hand in the santolina or French lavender. This is effective all through the year, with tiny silvery white leaves and stems, the older ones of which gradually become woody. The fragrance is not apparent until the plant is touched or brushed, and then a pungent aromatic odour, which clings to the fingers for a long time afterwards, is given off. Southernwood, or old man, is another though taller grower of similar class, that is so well known that further comment would be superfluous.

Anemone sylvestris, a foot tall grower, graces the month of June with its pretty nodding white flowers; while A. rivularis, which is half a foot taller, with large white flowers with conspicuous anthers, is equally desirable in May and June. A somewhat scarce plant is Jaborosa integrifolia, with very fragrant white flowers in June. This is a native of Buenos Ayres, forming tuberous roots and needing a sheltered and sun-baked nook if it is to do well. Not only are the flowers especially good, but the foliage is also very handsome and the plant forms a striking specimen that will appeal to all flower lovers. Adenophora lilifolia has many points to recommend it, for it is late flowering—July—pleasantly perfumed, and bears a profusion of blue flowers that reveal their close companionship to the campanulas.

THE WATER GARDEN.

Apart from the lilies, do not miss the water hawthorn—Aponogeton distachyon—a floating aquatic that is one of the loveliest of all. It blooms over a long period, producing large pure white flowers which are rendered still more conspicuous by the jet black anthers and which amply justifies the name of hawthorn in the delicious scent.

THE WATER HAWTHORN, APONOGETON DISTACHYON, WITH PURE WHITE FLOWERS AND HAWTHORN SCENT.

Among the nymphæas, some varieties are very fragrant while others are practically without scent at all. These we may divide into two classes—those of moderate dimensions and suitable for culture in small ponds, etc., and strong growers that soon cover a wide area of surface and which can only be grown where a broad sheet of water is available for their rampant growth. Let us deal with the moderate growers first. In Laydeckeri lilacina we have an especially free blooming plant with lovely rosy lilac flowers that are shaded with carmine and fade off to deep rosy crimson. The odorata group provides us with two fine forms, in alba and suavissima. Alba is exquisite, in pure white with medium-sized flowers that are freely produced over the entire summer; while suavissima is clear pink on long stalks that hold the flowers well out of the water. The perfume of this is beyond all praise and quite at the head of the odorata group. With a sheet of deeper water, the choice of fragrant water lilies can be tremendously extended and, did one wish to plant for fragrance alone, no criticism of the varieties of flower and foliage would ultimately be possible.

With small growers it is, of course, an easy matter to keep these near to the edge, so that their fragrant qualities may be fully appreciated; but with the more vigorous types this becomes increasingly difficult, although it is not a point that should be overlooked when considering their grouping.

Of varieties that can be specially commended, Carolinianum perfecta is splendid. This has large semi-double flowers of a delicate blush pink. Fulva, of medium size, is very distinct with yellow flowers shaded by pink and ultimately changing to orange red as they age, a feature that adds not a little to the charm of so many of our water lilies.

The Marliacea group provides us with two fragrant species—Marliacea albida, with gigantic white flowers and yellow stamens; and rosea, with large clear rose flowers that fade off to a lighter flesh pink. A new variety is Masaniello, with very large flowers of deep rose that becomes carmine on the edges of the petals. The contrast of these with the white sepals and yellow stamens combines to make up a very striking flower. Odorata gigantea is a noble form of this for a large sheet of water, and its huge white flowers and deep bronzy leaves together make a most effective plant.

SUSSEX.

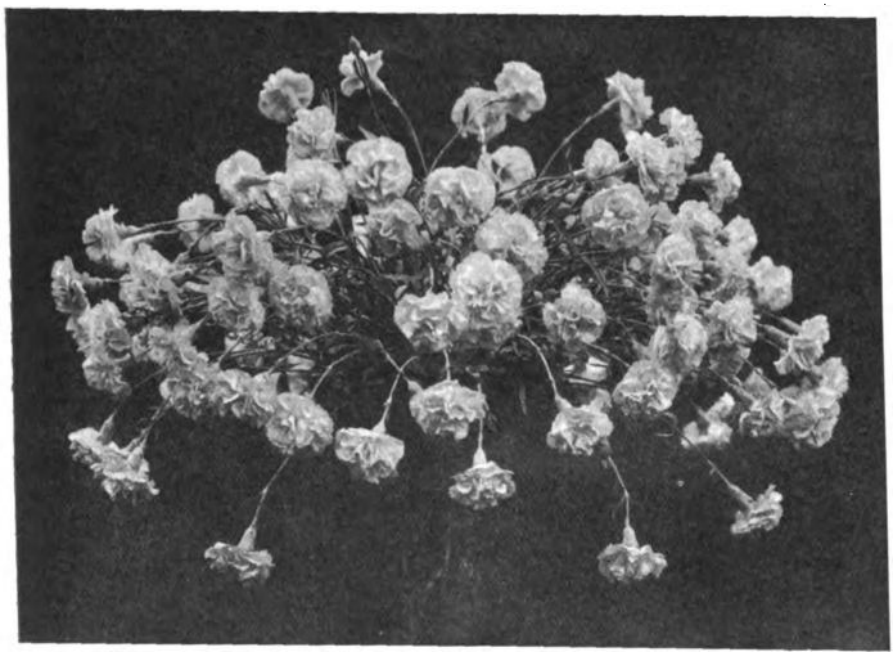
CARNATIONS OF THE FLORISTS' SHOP

THE most consistent flower in the florists' shop is the carnation, as every day throughout the year they are in abundance. It is the greatest commercial flower of to-day, for they are always obtainable. Yet if you enquire of a florist's girl the name of a variety or where it was grown, how seldom she knows.

Practically all the carnation flowers sold in the British Isles are produced in the home counties by large firms which specialise more or less in growing carnations only.

The perpetual-flowering type is the race almost exclusively grown for cut flowers; they are cultivated in very large greenhouses, the plants being planted out in beds or on shallow benches. Many of these plants flower perpetually from two to four years, producing from twelve to twenty-five flowers per year. The great secret in the successful cultivation of the perpetual-flowering carnation is to provide good light, and a fresh, cool, buoyant atmosphere of not exceeding 50° Fahr. at night.

The selection of varieties plays a most important part in the commercial production of carnation blooms, the variety must be free flowering and of a free, healthy growth, also the blooms must be of a good lasting quality and a saleable colour. Unfortunately, the flower salesman in Covent Garden Market, and in many florists' shops, often shows lack of enterprise in recognising or handling any new improved variety, and progress is retarded.



LADY NORTHCLIFFE, A POPULAR PALE SALMON.

To-day the most popular varieties as seen in the shops are:

Light Pink.
- Lady Northcliffe, pale salmon.
- May Day, flesh pink.
- George Allwood, blush salmon.
- Laddie, large pale salmon.

Dark Pink.
- Mrs. C. W. Ward, cerise.
- Master Michael Stoop, deep cerise.

White.
- Wivelsfield White
- White Enchantress.
- White Pearl (large white).

Crimson.
- Triumph.
- Topsy, very large.

Red.
- Aviator.
- Edward Allwood.
- Brilliant.

Yellow.
- Maine Sunshine, primrose yellow.
- Saffron, buttercup yellow.

Heliotrope.
- Mikado.

Apricot.
- Wivelsfield Apricot.

Fancy coloured kinds which sell in limited quantities.
- Eldora, white flaked red.
- Sunstar, yellow flaked red.
- Wivelsfield Beauty, apricot flaked bronze.

Some growers have seedlings of their own of which they will not sell stocks to the specialists for dissemination, preferring to hold the monopoly; while other varieties grow well only in certain districts, and thus never become generally popular.

Of course, when the amateur and private gardener grow perpetual-flowering carnations, as a rule, they are grown in flower-pots very similar to the method used in chrysanthemum culture.

The carnation suffers on account of the fact that people will imagine that they are difficult to grow—that they must have specially built houses. As a rule, those who fail do so because their plants have been coddled and killed by kindness, or the compost they used consisted of too elaborate a mixture. The soil must have free drainage. This is essential. Mix old yard manure and mortar rubble or slaked lime, and you may add a little sand if the soil is of too close a texture, also burnt ashes from garden refuse. Carnations love potash. The young plant should be grown under cool conditions, with a night temperature of about 50° Fahr.

The essentials for growing carnation plants are a strong light and a fresh, buoyant, cool atmosphere. There are no substitutes for these.

It is most essential that the plant should have a strong direct light, and only be shaded from the strongest sun until the young plant is established; this applies to all carnations. If you unduly shade a young plant, it has naturally a weakening effect. As soon as the young plant is established in the 3in. pot, pot on into a larger one, growing them in a cool, well ventilated greenhouse, with an abundance of light.

General horticultural knowledge has become so common that everyone understands the importance of stopping certain plants, and, without exception, every young carnation (the old border type excepted) should be stopped when in the 3in. pot. This should be done, on an average, at the sixth joint, and the plant should be growing vigorously when the operation is performed. It is wrong to pull out the point of the growth: rather should the top be removed just above a pair of matured leaves so that the remaining eyes are at an even state of maturity, and so produce a full complement of breaks.

It is a complex question where to grow your carnations during the summer for winter flowering. They are best cultivated under glass in a well ventilated light greenhouse, or under frame lights with a free circulation of air, although the common practice is to grow them out in the open, like pot chrysanthemums.

For the final potting a 7in. pot is big enough. For the compost for final potting, use one-fourth manure and sufficient sand to give a free drainage. Old mortar rubble or air-slaked lime is used in small quantities and benefits nearly all carnation soils, as also do wood ashes.

I do not favour leaf-mould for the final potting; it has a tendency to turn the soil sad and sour, and no carnation can grow in a sour soil.

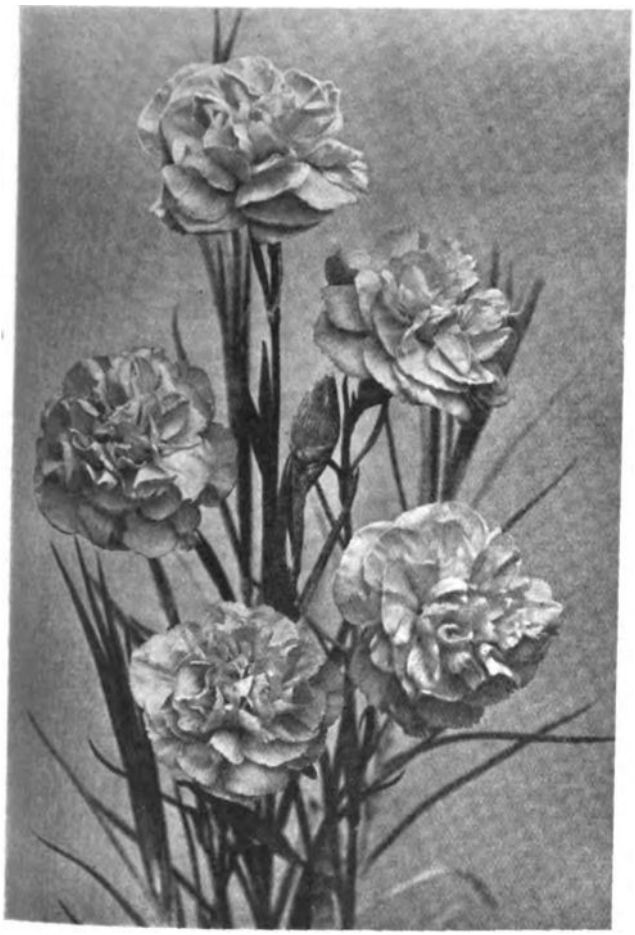
Now we come to the point of second stopping. Of course, this only applies to perpetual-flowering carnations for blooming in the heated greenhouse. The plants, having received their

Digitized by Google

first stopping in the 3in. pot, and the growths having attained a length of about 6ins., you again stop it in the ordinary way by pinching off the growth at the sixth joint from its base. When the next growth has reached the required length, you stop it, and so on, until the middle of July. The idea of that is to break up a cropping tendency. If a plant was producing six flowers at one time they would not be such fine flowers as if it were producing one flower, a bud just opening, another bud forming, and so on. If you break up the cropping tendency, you get a perpetual-flowering plant.

It saves time and is better for your plants if you use patent wire plant supports, because they allow the plants to grow naturally, producing finer flowers with stronger stems and healthier cuttings.

I believe in housing the plants in August for winter flowering. The winter treatment is very simple. In September we may get hot weather, and you would say, "Surely that must force them." That is not the point. Heat and light work hand



THE FINE RED EDWARD ALLWOOD.
One of the best of the florists' carnations.

in hand. If your greenhouse ran up to 80°, 90° or even 100°, it would not matter. If you had increased light and an abundance of air, you would not be forcing the plant. On the other hand, if you have a high temperature during the night, and no light, you will be forcing them. During the wintertime give as much air as is reasonable. At no time are our ventilators closed. We keep our houses at 50° at night in the winter. If you cannot do that, keep them at 40° or 45° in the winter, but you must be prepared for a slower growth. If you get plants stopped at the right time, you get buds set in the autumn before the dull weather comes. You must have night ventilation irrespective of the night temperature, and in this lies the crux of the whole matter.

All these little details, which may seem so prosaic, make for success in the cultivation of carnations, and more especially for the production of those fine blooms which beautify the shop windows of the leading florists in this country.

NOTES OF THE WEEK

CAMELLIAS: GROWING PLANTS IN THE OPEN AIR.

I AM now referring to those plants that are grown outside all the year round, planted out either as bushes or against high walls. It is generally accepted, I think, that camellias like an open position—that is, one fully exposed to the sun. I have had some considerable experience with these lovely flowering shrubs during the past forty years: experience gained in Lancashire and as far south as Hampshire. In Lancashire the specimens that I had to deal with were not quite fully exposed; they had been grown originally in an old conservatory standing by itself in a garden, but the roof fell in and the structure remained in ruins for many years, so I was able to note how the big bush fared, as I paid visits to it for the purpose of gathering the numerous magnificent flowers which it bore year after year. It was a white-flowered variety, double. There was not any protection afforded this specimen, and sometimes the blooms near the top were discoloured by frost. The plant was very healthy. In Hampshire there was for many years a group of fine bushes, averaging 10ft. in height and wide in proportion; they were nicely balanced specimens, grand as regards health of stem and leaves, but the flowers were not very fine individually, though they combined to make the group, as a whole, very charming. These bushes grew in a mixture of stones, peat and light soil on a slope facing due south, not protected except on the north side by conifers in belt form.

Another group of these bushes grew in the Bournemouth public gardens, in conjunction with palms and cordyline and the collection as a whole was most striking and interesting. The camellias flowered freely. Near Southampton I had charge of a large garden for many years in which camellias were grown on the north sides of two high walls. One collection was situated under the branches of large trees. The annual growth was moderate, but flowers nil. On the other wall, fully exposed to the north, the trees did much better and flowered freely. Being in a northern aspect, the flowers when slightly frozen escaped the morning sun's rays and were rarely spoiled. Putting aside all reference to the flowers of these shrubs, I think it is a pity that more of them are not grown in various positions in the open in the southern counties. The foliage is evergreen, the habit of the plant is naturally bushy and sturdy.

It is not wise to attempt to grow the camellia in soil in which there is lime; and in naturally dry soils a summer surface mulch is very beneficial to the roots. Plant young specimens—those that are full of vigour—and not old stunted ones from greenhouses, as they never become vigorous. —GEORGE GARNER.

A FINE HERBACEOUS PERENNIAL.

OF the comparatively large family of meadow sweets none is more useful to the gardener and garden lover than Spiræa Aruncus, more widely known perhaps as goat's-beard. A native of the sub-alpine woods and meadows of central Europe, it is of easy culture, asking nothing more than a moist, rich, loamy soil, consequently it is suitable for a number of positions in the garden. This herbaceous perennial is particularly effective in a shady border, grown either as a single specimen or massed; but it is no less handsome when bordering a path in the wild garden or wood, or beside a pool in a shady part of the water garden. It is especially beautiful when planted against a background of plants with a dark foliage, when the beauty of its delicate panicles is much enhanced by contrast. Attaining a height of 4ft., its wrinkled, serrated leafage, surmounted by ample sprays of creamy white flowers in June, makes it a very desirable plant. Once it is established it needs very little attention beyond cutting off the dead flowers just above the foliage, leaving this until it dies down in winter. As this plant objects to being moved or divided more often than is absolutely necessary, it should be allowed to remain undisturbed, except for the purpose of propagation, when it should be carefully divided in spring and replanted.—R. B.

SPIRÆA ARUNCUS IS PARTICULARLY EFFECTIVE IN A SHADY BORDER.

A GOOD DWARF RHODODENDRON.

AMONG the older dwarf evergreen rhododendrons none is more worthy of being widely known than R. ledifolium. It is twenty years since chance brought a specimen to this garden, and it has ever since been one of the most trustworthy as well as the most admired of spring-flowering shrubs. Though it will grow taller in more genial climates, as in Cornwall, the specimen referred to is not much above 30ins. high, spreading to 4ft. or 5ft. in diameter. The habit is somewhat

THE DWARF-GROWING R. LEDIFOLIUM.

dense, and the leaves, bright green above with paler undersides, are covered with hairs, especially when young. Buds begin to form at the ends of the twigs in April, or earlier, and shortly afterwards these expand into pure white flowers, usually borne in twos or threes. These exquisite blooms are each 2½ins. across and deliciously fragrant.

In habit, leaf and flower R. ledifolium bears a close resemblance to Azalea indica of our greenhouses. Indeed, it was at one time known as A. indica alba, and appears to be a Chinese representative of that species, though now accorded specific rank. For all practical purposes, at any rate, we have in R. ledifolium a hardy A. indica, with all the excellent attributes of that species. I have never known the shrub to be affected by frost (and we have recently had 22° on several consecutive nights), but the flowers are, of course, liable to be injured. On account of this latter we grow R. ledifolium under tall deciduous trees (this partly explaining the spreading habit of the shrub referred to), which do much to ward off the effects of spring frosts.

Comely and neat in general appearance, second to none in the beauty of its flowers and fragrance, hardy and easy enough in any fairly light lime-free soil, it is surprising that a shrub of such sterling merits that was introduced as long ago as 1818 is not accorded fuller recognition.—A. T. JOHNSON.

A NOTE ON SWEET PEAS.

IT may interest enthusiasts of this plant to read that a row of plants was staked here on February 8th. The seed was sown on September 25th. The plants are the picture of health and average 3ins. above the ground with tendrils showing, although it has been a cold, trying winter. This proves how thoroughly hardy this delightful annual must be, for the kitchen garden here, where the row is growing, lies low and is very cold. Every year I make a sowing round about the same date, as plants so raised begin to flower earlier than if sowing was deferred until spring—a very great boon where early

Digitized by Google

flowers are in constant demand. Quite apart from this gain in early flowering, however, is the fact I think that it emphasises the hardiness of the sweet pea.

Enquiries made have proved to me how few amateurs or gardeners realise the stout nature of this plant. One sometimes reads a list of annuals considered hardy for autumn sowing, but the sweet pea is not mentioned, although it would prove to be, in ninety-eight cases out of the hundred, the most virile. I am aware some sow in autumn in pots, keeping the latter in cold frames until spring, but such precautions are necessary only in the most bleak and trying of districts. The above sowing is supplemented by further sowings now and later on.—C. TURNER, *Ampthill Park.*

A DECORATIVE GREENHOUSE ANNUAL.

SCHIZOPETALON WALKERI.

THIS somewhat out-of-the-way and too seldom seen annual bids fair to become extinct, as some firms who used to list the seed do not do so now; but, if only for the pleasant, almond-like perfume the white flowers impart, it is worthy of attention. Scanning a catalogue, the name alone—rather a laboured one, it seems to me!—does not convey much idea of its value; but as an easily grown, simple annual, it should not be lost sight of. It is called the good-luck flower, and the one firm I have come across this year who are sending it out describe it as rare. I suppose it is the seed which is referred to, as my experience of it prompts me in saying that it yields little seed. A sunny border and light, well drained soil are all that it asks. If sown out of doors in May, or in the greenhouse in March or April, and the young plants hardened before being put out, "good luck" is almost bound to follow.—CLAREMONT.

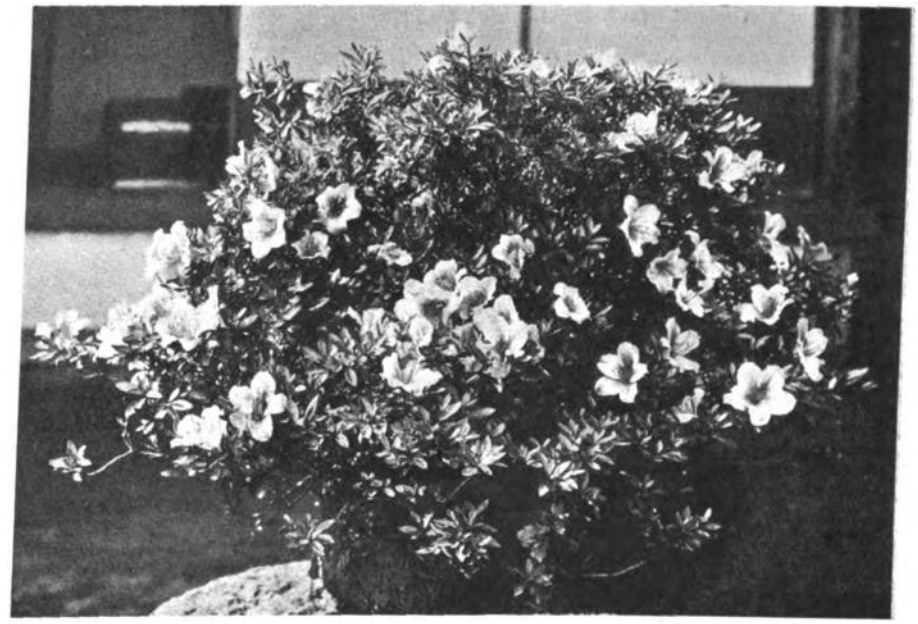
THE TRUE AZALEA INDICA.

THE real Azalea indica is almost unknown in British gardens, yet it is a pretty plant well adapted for moist, half-shady places in rockeries. It is a native of extreme south Japan, where it is a common fluviatile shrub growing from 2ft. to 6ft. tall and forming dense thickets on the banks and among the boulders of rock-strewn streams. Often it is decumbent or nearly prostrate in habit. The branches are very numerous, slender and rigid, clothed with narrow lanceolate to oblanceolate obscurely toothed leaves, which in autumn assume crimson and vinous purple tones. The flowers are terminal, either solitary or in pairs, broad funnel-shaped, from 2ins. to 3ins. across, bright red to scarlet, sometimes rose-coloured and always with five prominent stamens. The flowers are large for such a slender-growing plant, and the whole habit of the plant is singularly pleasing.

This was the earliest known Oriental azalea, and its name "indica" is indication of the ignorance in geography which prevailed at the time it was first known in Europe. A native of Japan, it never knew India. Carried by Dutch traders from Nagasaki to Batavia and hence to Holland, it was growing in the garden of Jerome van Beverningk at Leiden in 1680 and known as Chamærhododendron exoticum. It is figured by Hermann in his "Horti Academici Lugduno-Batavi Catalogus" (fig. facing page 142), published in 1687 under the name of Cistus Indicus. The figure is crude, but the plant is easily recognisable. It was on this plant that Linnæus based his Azalea indica, though there is nothing to indicate that he ever saw it in a living state. Apparently it was lost to European gardens when other azaleas reached England from China at the close of the eighteenth century and early in the nineteenth century, for these were given its name, and the confusion existing to-day dates from that period. The story is too intricate to be told in detail here, but the curious may read it in my book on Azaleas. Suffice to say the so-called Indian azaleas of to-day, so abundantly raised in Belgium, are the product of another species and have no right to the name they universally bear. The true plant was re-introduced into England in 1833, and for a decade was cultivated freely, but seems to have disappeared in 1850. The fact that it cannot be forced by strong heat to blossom out of season doubtless led to its being superseded by other sorts that admit of this treatment.

In Japanese gardens Azalea indica is still a great favourite, and some two hundred named forms are recognised under the native name of Satsuki-tsutsuji—that is, "fifth-month azalea," from the fact that it blossoms in June, which is the fifth month of the Chinese calendar. This azalea is planted on or among rocks, singly or in groups, and is used as a garden edging. It bears trimming well, and its naturally low dense habit makes it particularly useful in Japanese gardens. I admired it much in old burial grounds at Nikko and elsewhere; the plants were prostrate or nearly so, and, with their scattered large red flowers, strongly suggested the rock cistus, and one saw how very applicable was the name the ancients gave this plant.

In 1914 I sent seeds and plants of this azalea from Japan to the Arnold Arboretum, and these were distributed under the name of Azalea macrantha, the identity of the plant at that time not being established. Some of these have struggled through the severe winters of Massachusetts, and there is little doubt that the plant will prove quite at home in most English rockeries. In recent years odd forms of this azalea have reached England from Japan, and Millais mentions one or two. And since about 1877 there has been in European gardens an azalea with double flowers and known variously as A. Rollisoni, A. rosæflora and A. balsaminæflora. This is none other than Azalea indica with double flowers.—E. H. WILSON.



A WELL FLOWERED PLANT OF THE TRUE AZALEA INDICA.

SHOWY BORDER PLANTS.

THE genus liatris contains several species of the highest value for border decoration, and those who are at present building up a herbaceous border should not overlook their decorative capabilities. They thrive vigorously in all medium to light loams; they are not quite so good in heavy or cold soil. All the species may be raised from seed, if seed is procurable; sow now in the frame or in a seed bed. The flowers are borne in long spikes; of centaurea nature, they are set closely together and, as we have stated, they are very showy. L. pycnostachya, 4ft. high, has rosy purple blossoms in late August and September; L. spicata, 2ft., has erect, stiff spikes of purple flowers; L. dubia, 2ft., is rather brighter in colour; L. odoratissima is a dwarf, 9ins. high, bearing pink flowers of delightful fragrance. These are the best species.—LANARKSHIRE.

AZALEAS: A COMMON CAUSE OF NON-FLOWERING.

I DO not think that, among hard-wooded plants which bring colour and beauty to a greenhouse during the first few months of the year, so much neglect, after their flowering season, is shown as in the case of azaleas. This applies, mostly, to small growers, whose houses, being of moderate dimensions are crowded, often to excess, with other plants in preparation for their summer quarters, and, as a consequence, plants having finished blooming are placed either in a house with a much lower temperature or, worse still, transferred to a cold frame to take their chance. More than once I have been appealed to as to the "cause of my azaleas not flowering this year," and enquiry, in nearly every instance, went to show that plants, after flowering, had to give way to others coming into bloom, and were removed from a warm and genial atmosphere to one much colder, where, not infrequently, they were allowed to become dry. As azaleas contribute such a wealth of beauty to a greenhouse in the early year, nothing should be allowed to happen to prevent their blooming the following year. With this in mind, arrangements should be made for them to continue in warm surroundings after they have ceased to flower; watered as needed, and syringed to encourage the growth of new wood from which one has to look for the finest flowers another season. As is well known, in common with other hard-wooded subjects like epacrises, boronias, etc., azaleas are grown mostly in peat, which is of such a close, retentive nature that the amount of water which would be deemed sufficient for a fuchsia, for example, is quite

Digitized by Google

inadequate for these showy flowering shrubs, and whenever water is administered it should be done thoroughly. Azaleas in smallish pots may be plunged up to the rims for a short time to ensure the water reaching the roots. Plants are often starved out of existence because of the failure to appreciate how to water them properly, and at no time is it more important that this detail should be closely watched than now. Free, uninterrupted growth cannot take place, though azaleas are kept in the greenhouse, unless it is encouraged in this way. Syringing will do much for them, but that of itself is not enough. Those who study the best interests of the plants will so plan their work as to allow azaleas to remain in the house until they have perfected their growth, and not seek to put them in cold frames until towards the end of May. Their summer quarters should be a cold frame in a north aspect—where they can enjoy shade as well as sun for part of the day—with the lights off most of the time, and where it is possible to plunge the pots in a few inches of fine ashes which not only keeps the roots cool in the hottest weather, but also reduces, in a degree, the labour of watering. It is these details that go a long way towards ensuring a good display year after year.—W. LINDERS LEA.

CORRESPONDENCE

THE PRUNING OF SHRUBS.

SIR,—In your interesting editorial article on the above, your readers' experiences are invited on the subject. Surely the pruning of shrubs must be governed by their growth and flowering qualities. Some shrubs make rampant growth in some localities and are practically at a standstill in others; for instance, here, Eupatorium Weinmannianum flowers every autumn and never makes much growth, and the same shrub I have seen severely pruned in some gardens to induce it to bloom.

We find shrubs like Malva olbia and shrubby veronicas must be pruned hard to save them dying back; at the same time, we have never pruned Potentilla fruticosa.

Forsythia suspensa in these gardens responds to heavy pruning; but Viburnum fragrans has never been cut and never fails to blossom.

Erica mediterranea we prune carefully, as it makes a large shrub here and gets ragged if not cut; the same applies to Olearia macrodonta; but OO. stellulata and Haastii are never touched.

We find all the cistuses repay for careful cutting, and so do most of the elæagnus. Clianthus puniceus is another shrub we prune fairly hard; teucriums also pay for cutting.

We find in most cases that the best time to prune shrubs is immediately after their flowering period, and, in the foliage shrubs, the early autumn.

No doubt, the secret of the whole thing is knowing one's shrubs and their capabilities.—R. MOORE, *Thorpe Hall*.

[Our correspondent has certainly stated the case correctly when he says that the pruning of shrubs must be governed by local conditions and in stating that the secret lies in knowing one's shrubs. The latter was one of the points on which I tried to lay stress: few gardeners take the trouble to know their shrubs.—ED.]

FEDGES.

SIR,—Ivy fences, which Mr. Elliott calls Fedges, were in use many years ago. They let no wind through when old and therefore have to be strong enough to resist the wind. Instead of split chestnut, posts as thick as gateposts should be used. There were several "Fedges" in a garden I knew for over forty years, but they have nearly all disappeared. They were probably planted about a hundred years ago.—G. B. COPE, *Wolverhampton*.

"NEWER AND BETTER GLADIOLI."

SIR,—In the recent article, "Newer and Better Gladioli," "C. H. A. S." in mentioning the "mixed medley types and species, crossed and intercrossed, forming the ancestry of modern varieties," expresses the opinion that the resulting divergence in form and habit shown by present-day kinds is desirable rather than the reverse. Weighing up the pros and cons, this may be so; but is there no standard by which the merit of either the large-flowering or the primulinus hybrid varieties may be judged, or is it purely and simply a matter of personal taste as to what may be considered good form in either section? Judges at exhibitions, of course, must have an ideal, and I should like "C. H. A. S." to give us what he considers good form in modern gladioli, for I feel sure many of your readers, like myself, have rather foggy ideas on the subject.—A LOVER OF GLADIOLI.

WHAT'S IN A NAME.

SIR,—A name should at once give a clue as to what the flower is like, and as colour is one of the chief points by which to remember it, I think a clue as to its colour is of importance. Mrs. John Smith gives no clue. Golden Queen does. Yet, as Mr. J. MacGregor says, kings and queens are overdone. So a better name, more distinctive and equally descriptive, should be found. Mr MacGregor gives a list of names of roses as being memorable and distinctive; but I do not think some of them are descriptive or can convey much to anyone unacquainted with them; for instance, what colour, form or habit does Colleen, La Tosca, Janet's Pride, etc., convey? They are distinctive, but that is all. Our ancestors may have chosen haunting names, but what *do* any of these convey? Sweet William, London Pride, Traveller's Joy—pretty and original, but not descriptive. Yet I do not want to get back to the Golden Kings and Queens and Snow Kings and Queens and all the Lady This and Mrs. That; but the descriptive, original and distinctive names are difficult, and as a raiser's job is to name his plants, he knows the difficulty and gets over it easily by using the Kings and Queens and Perfections and Glorys, and so saves himself much worry and thought. As a raiser of new plants, I know the difficulty, and I am guilty and plead guilty to the charge of using personal names. The Editor mentions Primula Mrs. Berkeley as being inaptly named and conveying nothing to the uninitiated. It should have been Primula *pulverulenta* Mrs. Berkeley, which would have given a little more information, but not enough. As the raiser of the fertile forms of this primula, I should like to have some suggestions as to what I should have named the varieties I raised to give them original, distinctive and descriptive names. A rich rose pink is named Lady Thursby—named on account of the encouragement given by her to me in raising this strain. Hew Dalrymple, a pink with a dark crimson eye (should it have been named Dark-eyed Sue?), named after the raiser at the suggestion of several friends, to commemorate the raising of this strain.

I would welcome suggestions for better names, though I cannot change the name of the first one.

I am now at the beginning of the freesia season and hope to have several worth naming in yellow and mauve shades. I named my new variety "Wistaria" on account of its likeness to Wistaria sinensis. This described it very accurately, but a fellow freesia raiser objected to the use of the name of any plant or flower.—G. H. DALRYMPLE.

[I am tempted to try my hand at suggestions for names. Pink primulas: Strawberries and Cream, Coraline, Cherry Ripe. Yellow freesias: Yellow Locks, Orangeade. Mauve freesias: Woodsmoke, Plum-Bloom. Although not strictly accurate, they might give some idea of the colour.—ED.]

SIR,—In THE GARDEN of February 27th Mr. J. MacGregor of Cumbernauld has opened a subject, on the nomenclature of flowers, which I am sure must be of great interest, and will be welcomed by many readers of this paper, myself included. As a commencement has now been made and backed by the Editor, I think this subject ought to be thrashed out to a finish. The appalling yearly increase of florists' plant names is not only confusing and senseless, but really very often most perplexing to many when making a selection.

Antirrhinums I have particularly in mind as I write. Their names are legion. One may be the proud possessor of quite a number of distinct names, the plants showing little difference in form. Black Prince, Carmine Queen, White Queen, Coral Queen, indicate the colour of the flower, and little mistake can be made when giving an order for such to a good seedsman. Such names as Captivation, Admiration, Exquisite, Beauty and Charm in themselves carry no meaning as regards colour.—WM. GRANT, *Crathes, Kincardineshire, N.B.*

DAPHNE LAUREOLA.

SIR,—In the course of the discussion that took place in THE GARDEN a year ago about the scent or scentlessness of the flowers of the spurge laurel, I stated that, although I remembered enjoying their fragrance in my youth, I could detect none in the plants which grow and seed themselves pretty freely in the woods here. That statement I must now amend, because on March 1st, in passing through a wood about sundown, I found the flowers deliciously scented. But on March 4th and 5th I could not detect the slightest fragrance in the flowers on the same bushes as I tested on the 1st inst. I have tested several bushes again to-day, and neither I nor a lady who was with me could detect any fragrance, nor do the flowers emit any scent after standing in water in a warm room.—HERBERT MAXWELL, *Monreith*.

MONTBRETIAS.

SIR,—In the issue of THE GARDEN, March 6th, there is an unfortunate slip, which you, no doubt, will be pleased to rectify. In Mr. J. Coutts' article on montbretias, page 143, second paragraph of the article, he says that the Montbretias Nimbus, Lemon Queen, etc., were raised by "the late Sidney Earle of Earlham." They were, in point of fact, raised by my old friend Mr. Sydney Morris, J.P., D.L. of Earlham Hall, Norwich.—F. HERBERT CHAPMAN.

[We thank our correspondent for pointing out this error.—ED.]

FROST AND SOME SHRUBS.

SIR,—The sharp frosts of this winter have taken a heavier toll of shrubs than was apparent a month ago. Buddleia globosa has suffered badly with me and my largest plant killed. Olearia stellulata has died back to ground level. Ceanothus divaricatus, a vigorous bush 7ft. high, is dead, as also are Polygala latifolia, Desfontainea spinosa and Andromeda floribunda. A good specimen of Abutilon vitifolium lost every vestige of leaf, but is now shooting from every tip and is little the worse.—E. BROWN, *Kent*.

RHODODENDRONS IN VARIOUS AREAS

BELOW will be found an attempt at tabulating the success or failure of rhododendron enthusiasts in various areas of the British Isles in growing different rhododendrons, both species and hybrids. Naturally, such a survey is by no means conclusive, for various reasons: the situation of the various gardens may not conform to the standard of the district, in that they may be more sheltered or more exposed, have different degrees of sun heat or of moisture to the average garden of the neighbourhood; also, individual plants may be placed in more advantageous positions than others; also, the various readers who so kindly gave us of their experience may have different ideas of their success or failure with a plant—standards are never the same. On the other hand, even after making allowances, certain useful information is crystallised in these columns. They show, for instance, that certain species are uniformly successful throughout the country, such as Augustinii, calophytum, campanulatum, sutchuenense, which every list includes, and a number with, perhaps, one "fair" to eight "goods." They also show that rhododendrons of the campylocarpum and Souliei types thrive better on the east coast than on the west, and that, as a rule, dwarfs such as intricatum flourish better in the colder north than in the warmer south. Those unmarked have not been attempted in the area concerned.

BOG PRIMULAS IN WINTER

ONE often hears of these striking primulas as being only biennial or prone to die after flowering. While not contradicting this statement entirely, I am, however, of the opinion that many of them are far more permanent than generally believed, if only they are watched carefully during the winter months.

Most members of this group, with the exception, possibly, of P. secundiflora and P. vittata, loose their leaves entirely at the first autumn frost. These leaves collapse in a nasty, juicy mess around the crown. Opinions vary as to whether this mess ought to be left during the winter or not. On the one side it is said that nature is giving the crown a protecting covering and so the mess ought to be left. But that is all very well in the plant's native habitat, where a thick mantle of snow probably covers the crown and keeps it dry and dormant during the winter. From watching the results of leaving this mess in our own climate I have come to the conclusion that it is far better to remove it at once. If left, it forms a welcome shelter for slugs while they consume the crown, and also the mild wet days we so often have, tend to make the rotting process spread from the leaves to the crown.

Turning now to the dormant crown of the plant, if it is examined carefully it will be noticed that all the roots have also rotted away to within an inch or so of the base. This, consequently, leaves the crown very loosely planted in the soil. Also the shrinkage of the dead leaf-stalks tends to separate the soil from the crown itself, leaving it as it were loose in a little pit, in which water collects. Now, when any plant appears to be sickly or loosely planted, the birds will nearly always pull it out of the soil, thinking, no doubt, that a loose plant means a fat grub among the roots. Consequently the dormant crown may often be found lying loosely on the surface some distance away from its original site. It then becomes a certain prey to slugs, and if it survives their appetites, when the warm weather comes it will shrivel and die, and be pronounced "Biennial."

If on the other hand birds and slugs leave the crown alone, which is very unlikely, there will sure to be occasional frosts which will also lift it out of the soil to take what poor chance it may have of re-establishing itself later.

From these points, I think, it is quite clear that an occasional look round the bed where these plants are grown, will be sufficient to bring most of them successfully through the winter to another flowering period. First of all, the dead leaves must be removed and when the roots have rotted and the crown is loose, I advise lifting it completely and replanting firmly at once. Needless to say, this is a most suitable occasion for division of a large crown. After every frost a further inspection should be made and all loose crowns made firm again.

P. secundiflora and P. vittata differ slightly in that the crown retains a certain number of leaves throughout the winter months. Apart from this fact, however, the habit of the group in shedding its roots is still present. When the roots are separated the basal leaves form yet another factor in lifting the crown from the soil, for they show a marked tendency to curl directly downwards, thus lifting the crown high and dry. Further than this, when the crown is raised from the soil, the tips of these leaves curl right round beneath it until they touch the tips of the opposite leaves. This, of course, turns the crown over on to its side, and any strong wind may blow it a considerable distance away. If an attempt is made to replant the crown, much difficulty is met by the rigidity of the curled leaves, and it may be necessary to cut them off before the crown can be made firm. Before replanting any crowns a careful search should be made on the underside among the root stumps, as slugs often eat themselves into little holes at this spot, and, of course, will soon destroy the whole crown if not removed.

P. involucrata and its allies also form leafless crowns during the winter months, but in these the roots do not die. The root system here is entirely of the surface type, the roots themselves being thin and short, and having very little hold on the soil. Consequently, the crowns are nearly always lifted clear by the slightest frost, and worms will often drag them upside down into their burrows, so that the threadlike roots are left waving in the air. Needless to say they must be replanted at once, and in doing so it is wiser to place the top of the crown half an inch below the surface of the soil, in order to prevent further lifting during future frosts.

The muscaroides section appears to be quite different from the previous ones, in that the chief enemy is insufficient drainage and too much wet. Plants of this group should be grown in perfectly drained situations and should be covered with a pane of glass during the winter months.

The most difficult enemy to cope with when growing any of the bog primulas is the eel-worm. This insect riddles the crowns just at the moment of flowering in the height of summer, with the result that the flower-stalks and leaves suddenly wilt and die, and the crown itself becomes a wet, sticky mass of rottenness. The worm multiplies rapidly in the soil and should a plant be attacked, no further plants should be grown in that situation until the soil has been treated with a good steriliser or fumigant.

I hope that these few notes may prove helpful to lovers of these beautiful plants, who, like myself, have experienced difficulty in bringing them successfully through the vagaries of our winter months.

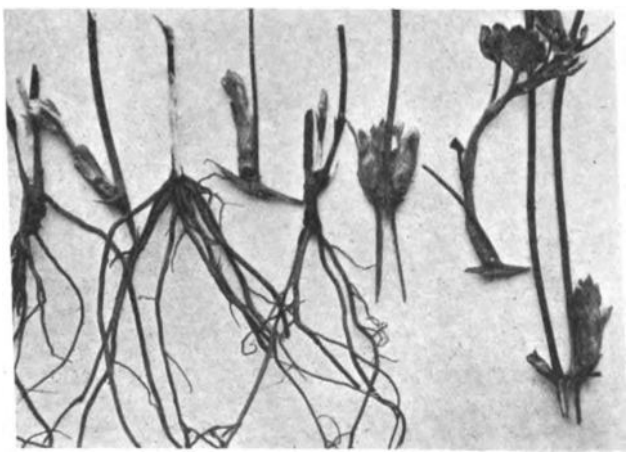
Canterbury. H. STEWART WACHER.

GARDEN TECHNIQUE

THE FLOWER GARDEN

CLEMATIS FROM CUTTINGS.

FROM two 4½in. pots of clematis cuttings inserted last February I have just potted up twenty-four good plants, and as the time will soon be here when good cuttings are again available it may be as well to remind lovers of the clematis that cuttings of these are by no means as difficult to strike as is generally imagined.



TYPICAL CLEMATIS CUTTINGS SHOWING METHOD OF ROOTING.

I have photographed three of the young plants mentioned above, together with cuttings typical of those which produced them, and with all of which I have been successful, but at the time of taking the photograph it was not possible to find shoots quite long enough, with the exception of the third from the right, and this must be borne in mind by those who may be persuaded to try this method for the first time. I prefer as cuttings the new growth when from 2ins. to 3ins. in length with a slice of old wood an inch or so in length, and on the Jackmanii varieties there will soon be plenty such to be had.

Examination of the illustration will show that roots are emitted from the old wood as well as from the node itself, similar to the grape vine when propagated from eyes, but, of course, the vine eyes are used when dormant.

The type of cutting shown on the extreme right is, perhaps, not quite so successful as the others, but as there are plenty of them to be had at pruning-time, and as they can be inserted thickly in the pots, they may as well be tried as thrown away. When the new growth is sufficiently advanced for use prepare as many pots as are wanted with good drainage and a compost of loam with plenty of sharp sand and a little lime rubble or finely crushed oyster shell, commandeered from the poultry supply, incorporated. Prepare the cuttings and insert firmly and well water them in. Plunge the pots to the rim in ashes in a shady place—against the north side of a wall is an excellent position—and cover with a hand-light. Here they will remain for several weeks, due attention being given to watering when necessary. Aim at keeping the soil always moist, but never in a sodden state.

In early summer take out and examine some of the cuttings, and when it is found that a good callus has formed air may be gradually admitted and after a week or so the hand-lights may be removed, leaving the pots plunged where they are until the approach of winter, when they may be removed to the shelter of a cold frame, and when the young growths appear above the soil towards spring the young plants should be very carefully shaken out and potted separately in small pots in a similar but less gritty compost to that used for the cuttings. Keep the young plants in the cold frame until they can safely be placed outside, but do not coddle them in any way.

As there is usually very little or no visible progress made during the first year, propagation of the clematis from cuttings is obviously much too slow a process for commercial raisers who have to provide plants as quickly as possible in their thousands, and for this reason they use the wild clematis as a stock on which to graft the better kinds, this being the readiest way of obtaining rapid increase, and around this practice, controversy has raged for years, some well known cultivators holding the opinion that the use of this stock is responsible for the disease which causes the wilting and sudden

Digitized by Google

collapse of young plants. When buying grafted plants from the nursery to add to their collection see that they are planted deep enough to bury the point of union with stock and scion below the surface of the soil and very soon the plant will be on its own roots. —H. C. W.

PRIMULA SINENSIS.

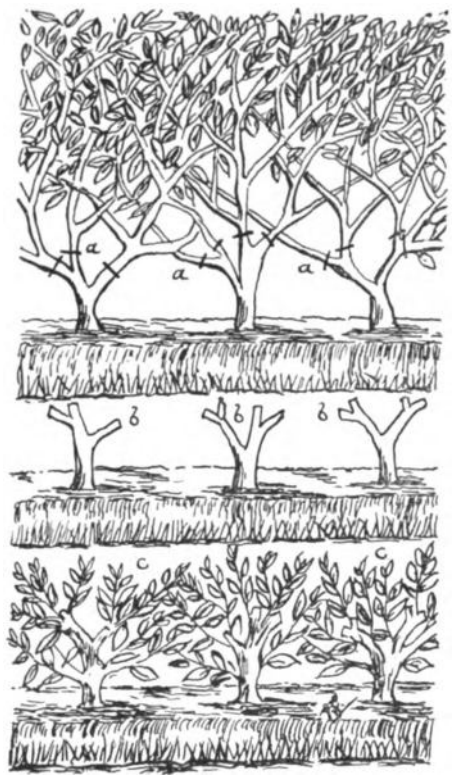
AMATEURS a generation ago were not eager to grow primulas unless they had a good artificial heat available. Certainly, the plants do very well where heat from pipes can be commanded at will; but, unless some amount of forcing is to take place in the late wintertime, the plants will thrive better without being subjected to a high temperature. They like a little artificial heat while young, if the seeds are sown early in the spring; no artificial heat when raised in May, and only sufficient throughout the winter to keep the atmosphere buoyant and the plants safe from frost. A mixture of good fibrous loam and leaf-soil in equal quantities and a nice sprinkling of coarse, clean sand or old powdered mortar will constitute a suitable compost in which to sow the seeds. A similar compost, in a rougher state, will answer for the first potting of the resultant seedlings. Pans or pots are best for raising seedlings in, and both pots and crocks must be clean and dry when used. A thorough drainage is essential. Three parts fill the pot or pan with the compost, make it level with a piece of dry board, or the bottom of an empty pot; apply water and allow the soil to settle for one hour before sowing the seeds thinly—about 1in. apart. Cover the seeds ¼in. deep, place a sheet of glass on the pot, also some brown paper. Maintain the soil in an even state of moisture, and wait patiently for germination to take place. Germination is irregular, so it is wise to lift the forward seedlings carefully and wait awhile for others to appear before discarding the pot or pan of soil.

CANNAS.

THE canna has been very much improved during the past few years. Thirty years ago there were not many varieties in cultivation and the plants of these were rather tall-growing and bore indifferent flowers as regards substance and quality. Now we have some very beautiful varieties, possessing good substance of leaf and flower. The plants are dwarf-growing and their leaves are highly ornamental. For filling flower beds in the summer these plants are valuable as the foliage is so rich and effective. Roots that have been stored in sheds during the winter months soon make substantial growth when subjected to a greenhouse heat. Very early forcing into growth of the new leaves is not advisable as the latter, unless exceptionally carefully dealt with in frames prior to being planted out, will become weakly and drawn and very liable to injury when fully exposed to strong winds. The treatment of the roots should be very similar to that suitable for dahlias. The present is a good time to purchase canna roots. After the new roots appear it is advisable to place each plant separately in pots and from the latter plant in the flower border. Specimens that are to be grown and flowered in pots in the greenhouse should be started in the pots and be once repotted, this taking place just before the flower spike appears. Canna seeds are hard, and should be soaked in water for two days before sowing and, until germination is complete, the soil should be kept consistently moist. Sow in heat, a gentle bottom-heat, if such is available.—GEORGE GARNER.

THE TREATMENT OF OLD LAURELS.

ONLY too soon the old neglected laurel hedge becomes unsightly and useless as a fence and of very little use as a windbreak, because the wind blows through the leafless lower stems in a cold current. Such cold draughts of air, blowing upon tender plants near, are favourable to the spread of mildew and insect pests, especially aphides and red spider. The present is a suitable time to cut back old leggy specimens. By the end of the year new shoots will have formed a nice bushy fence quite 3ft. high. My remarks apply to both the common and Portugal laurels. Sometimes it is found necessary to move an old hedge forward or back a few feet. Many years ago I assisted in the work of lifting and replanting a Portugal laurel hedge from its old position to a new line 6ft. back. The plants were old, some of the stems measuring 6ins. in diameter. All were cut down as shown in the accompanying sketch, sufficient soil excavated around the roots, some of the latter cut off and the mutilated specimens duly levered to their new positions. At the end of two years



the laurels formed a very fine compact hedge. The dark cross lines at *a*, *a*, *a* in the sketch show the operator the approximate height at which he should saw off the branches. Smooth the cut stumps with a sharp knife. When the cutting is finished the stumps will look like those shown at *b*, *b*, *b*, and at the end of the year like the sketches *c*, *c*.—HANTS.

HOLLYHOCKS.

THERE are few flowers that add to the charm of a garden, especially an old-world one, more than the hollyhock does. Grown in clumps amid shrubs and trees, or in beds with a shrubbery background, the stately stems well clothed with richly coloured flowers look very beautiful. The dreaded rust almost stopped the cultivation of the plants many years ago. Then our florists began to raise plants from seeds, mostly single-flowered at first, and the seedlings, being robust, resisted the disease. Now, we may sow seeds and reasonably expect a big percentage of plants bearing double flowers. Those who are growing old plants should treat them well. I find that specimens growing in a poor rooting medium fall victims to the disease sooner than those grown in a rich soil made moderately firm. Prepare the soil now and plant the hollyhocks at the end of March or early in April. In the latter month where the soil is heavy, as it is so essential to success that the plants grow freely and strongly right from the start. First decide as to the positions in the borders, then take out the soil to a depth of 18ins., put in some well rotted cow manure or farmyard manure mixed; thoroughly incorporate the manure with the soil till the hole is filled up again. A space of 2ft. across so treated will accommodate three plants. Old plants wintered in the border should have the surface soil around them removed and good fresh soil and rotted manure mixed placed on as a surface dressing. Seedlings resultant from seeds sown recently should be grown on strongly in a firm bed of good soil in a cold frame. Before they become overcrowded replant them in outside beds.—CHRISTCHURCH.

TRANSPLANTING HALF-HARDY ANNUALS.

PRIOR to the final planting of these lovely annuals in their flowering quarters, it is necessary to transplant the seedlings of the majority of the kinds once in boxes of soil or in a bed in a frame. We will presume that readers now possess seedlings in pots or boxes. They should make up a compost of loam and leaf-soil with sand or old mortar rubble added. This compost should be placed in a box or formed into a bed in a cold frame. Make the soil moderately firm while it is in a fairly dry condition and transplant the seedlings, generally 3ins. apart each way, and firm the soil around the roots carefully so as not to injure them or the stems. Always lift the seedlings with a pointed stick or trowel so that all their roots are retained practically intact; place them in the new soil in a similar position with roots straight down. Stocks and asters sometimes damp off in their seed quarters; directly any such damping occurs, get all the sound ones transplanted, or they too will damp off. Do not merely sprinkle the newly planted seedlings, but apply a really good soaking through a fine-rosed watering can, then wait until the soil is again becoming dry before applying more water in a like manner. Some shade may be necessary: but it must not at any time be excessive, as weakly plants are almost useless for planting out. Gradually harden the young plants by taking off the lights from frames in fine weather during the day time, and all night, too, after the third week in May. Plants in boxes should be placed in a sheltered position outside early in May and protected by placing stakes over them to support sacks or similar covering material. Partial exposure for a fortnight, then day and night exposure for a week and the plants will be in a fit condition to plant in the borders where they should, in due course, make a fine display of blossom.—G. G.

FRUIT & VEGETABLES

SPRING PLANTATIONS OF STRAWBERRIES.

STRAWBERRIES succeed better in some districts when plantations are made in April. Of course, they bear no fruit the first season, but a crop of small vegetables may be taken between the rows. The plants are well established and produce a fine crop of berries the second season.

The strawberry plot should be well prepared. If the soil is light or sandy a heavy dressing of farmyard manure may be applied when the ground is dug or trenched. In the following seasons when the plantation is forked over or hoed and weeded, in the springtime, further dressings of farmyard manure may be given between the rows, as a mulching.

Digitized by Google

If manure is plentiful, this mulching may be at the rate of a barrowload to a row of about 10yds. to 15yds. in length, or even heavier. This heavy mulching serves to conserve the moisture in the soil, and only in the event of a severe drought will watering be needed when the fruit is forming.

When planting, draw light drills with a hoe and plant carefully. Spread out the roots in their natural position and cover lightly with fine soil. Tread firmly. Allow plenty of room between the plants, say 15ins. to 18ins., and keep the rows 24ins. to 30ins. apart. Nothing is gained through planting too closely.

Autumn plantations may now be looked over and the soil made firm around the plants. Any vacancies caused through plants dying off should be filled up. For this purpose, it is well to have a number of runner plants laid in, or planted as in a nursery bed, in some convenient corner. These are easily lifted with a ball of soil at their roots and scarcely suffer any check from being transplanted.

Where cranefly grub (or leather jacket) is troublesome, scatter around the plants a handful or two of broad bran moistened with water and mixed with a dusting of Paris green.—J. W.

EXHIBITING AND EXHIBITION POTATOES.

TO any reader of THE GARDEN who is an intending exhibitor of potatoes during the coming season of shows, I can very earnestly recommend the following list of twelve names as varieties which have just that kind of special merit in form, depth of eye and good skin which so very much helps to catch the judge's eye. In exhibiting potatoes, it is a very essential factor in the setting up of either single dishes of from six to twelve of any one variety, or of collections of six, eight or twelve distinct varieties, always to remember that judges of experience soon observe where there is class of the right sort, in either the single dish or collection sections; so always aim at growing the true type of exhibition potato. The white kidney classes at most shows are generally considered of greatest importance, so I give the five following, as having all the qualities of what a white kidney should be: Sharp's Express, Main Crop, King George, Improved Up-to-date and, in the writer's opinion, Sutton's International, as one of the most beautiful of all white kidneys ever raised for exhibition purposes. King Edward and a newer one named Catriona, which has purple markings about the eyes, are two of outstanding merit, to be exhibited as any other variety kidneys, not white. The pink eye marks of one, against the purple of the other, with their other high-class merits, put them in the front rank of exhibition dishes. In the class for pink kidneys, I cannot pass Mr. Breeze, as a beautiful pink kidney in all particulars; get the true type, and it has no equal for giving colour as a single dish, or in a collection of either six, eight or twelve varieties. Round whites: this class of potato is none too common for selecting true round types, therefore I only suggest two which have all the points needed to place them in the class as true rounds. Arran Comrade and that grand old favourite, Schoolmaster; nothing further said could enhance the value of these two. As a round pink, Kerr's Pink needs no further endorsement; grow plenty, and no trouble will be found in getting satisfaction. Golden Wonder has come to stay as one of the very best for a collection of dishes up to twelve, or in a single dish class as any variety round. The foregoing list, if grown under ideal conditions of culture, which is a very necessary factor in the art of exhibiting such a high-class vegetable, cannot fail to give the best results in the right sort of awards from the show boards, which all true exhibitors covet.—V. H. LUCAS.

NEWNES'

"HOW TO GROW"

GARDENING SERIES

Handy Pocket Size. : : : : : *Three-Colour Covers.*

EDITED BY WALTER BRETT, F.R.H.S.

(*Editor of "The Smallholder."*)

No. 1.—ROSES

Takes you through all the operations that fall to the lot of all who would grow the Queen of Flowers to perfection, explaining them so simply that future mistakes are impossible. Gives not only the practical principles of planting and pruning, but information on raising your own rose trees, growing roses in the greenhouse, etc.

No. 2.—PANSIES AND VIOLETS

Covers a group of garden plants—pansies, violas and violets—without which no garden is considered complete, giving those intimate details, those little "professional" secrets which enable those who know them to grow so much more perfect flowers, to have them in bloom from the earliest to the latest moment—violas to go along with the bulbs of spring, violets in the depth of winter.

No. 3.—SIMPLE FLOWERS FROM SEED

Tells you how to grow to perfection the flowers to which half the gardens of the country owe their summer and autumn beauty—those that can be raised with a minimum of trouble from seed. Enables you to make of the hardy annuals—whose seeds so many buy in packets—plants so big, so free-flowering, so decorative, that they are hardly recognisable to those who grow them in the ordinary way. Shows you how easy and economical it is to raise from seed many of the plants usually bought as roots.

No. 4.—DAHLIAS AND BORDER FLOWERS

The pride of every gardener is his mixed border. This book gives those secrets that enable the professional to contrive such a striking border display, so continuous a succession of flowers, such artistry in his grouping and his colour schemes—at such a modest outlay. The book also explains the whole art of growing dahlias to perfection—and dahlias, with their adaptability (there are dwarf sorts now to use in the summer bedding schemes as well as those tall kinds that make such a blaze of colour in autumn) and their great utility, are to-day ranking among *the* most popular flowers.

No. 5.—SWEET PEAS

Prized as they are for their fragrance and beauty, sweet peas are seldom grown in the ordinary garden as they should be—with big, perfectly formed flowers, three or four to the spike. This book tells you why not, corrects your faults, puts you on the right road and keeps you there. It places at your disposal all the discoveries which enable the professional grower to produce not only perfect sweet peas but a continuous succession of them from early summer to late autumn.

No. 6.—CARNATIONS AND PINKS

Besides explaining all the cultural operations, introduces you to new schemes that will make these most popular among flowers more than ever your favourite, more than ever useful to you, more than ever a striking feature in your garden. Gives special directions on growing carnations so that you may have them in bloom at seasons when they are considered the rarest luxury.

The ATCO TURF CULTIVATOR

The ATCO TURF REPLACING WEEDER

The ATCO LAWN EDGE TRIMMER

THE

ATCO

TURF CULTURE SPECIALITIES

IN the ATCO Range of Specialities every need of the lawn culturist is provided. The ATCO Motor Mower is the most economical, most dependable means of mowing without manual labour, and this year a complete range of models from 14in. to 30in. is offered at prices to suit everybody.

The success of the ATCO is best demonstrated by the fact that over 10,000 are now in use. The ATCO Turf Cultivator, for use exclusively with the ATCO Motor Mower, aerates the grass roots, eliminates moss and weeds and maintains the health of the turf.

ATCO Motor Mowers, the ATCO Cultivator, the ATCO Turf Replacing Weeder and the ATCO Lawn Edge Trimmer are all described in our 1926 Catalogue. Copy will be sent free on receipt of a post card.

ATCO MOTOR MOWER

PRICES From 30 GUINEAS

CHAS. H. PUGH
LIMITED
Whitworth Works,

31, Tilton Rd., BIRMINGHAM

Let us demonstrate the ATCO Motor Mower on your own grass without obligation upon your part.

KILL those WEEDS!

You want to keep your paths clean and yet, quite naturally, you do not relish that back-aching job of hoeing up the weeds. You can completely destroy the weeds and avoid that laborious task by using

COOPER'S

Weedicide

Which is used at a dilution of 1—100 and "Highly Commended" by the R.H.S.

One gallon of Weedicide is sufficient to treat 300 to 400 square yards. The cost of the ready for use mixture is about 1d. per gallon.

Write for our illustrated leaflet *"The Weed Problem Solved"* and you will see how quickly and easily you can clean your garden paths.

You may prefer to use a non-arsenical weedkiller and in that case there is
McDOUGALL'S PERFECT SAFETY WEEDKILLER

If unable to obtain locally, please write

COOPER, McDOUGALL & ROBERTSON, Ltd.,
BERKHAMSTED.

FOOD FOR YOUR GARDEN

SOME GOOD HYBRID RHODODENDRONS

IT may be of interest to gardeners who wish to start growing rhododendrons to have a small list of general favourites at hand: and by general favourites I not only mean those which are of the finest colour and good trusses, but those which are easy to grow and give general satisfaction year after year with a wealth of flower, provided, of course, that they are dead-headed and mulched every year with peat moss or old leaves and rotten wood. Provided that they are well planted at the start in well worked ground with good drainage, there is no reason why these hybrids should not flourish in full sun, although the best position for them is undoubtedly that in which the sun's rays do not fall on them throughout the whole of the long summer days. This is by no means a complete list, and, doubtless, many enthusiastic rhododendron authorities would add to it or remove some of the hybrids listed; but, on the whole, these plants have been tested in many gardens throughout the country and have proved eminently satisfactory.

DEEP REDS.

Ascot Brilliant.—A fairly early flowerer, but a fine red crimson in a large, well shaped truss.

J. G. Millais.—A particularly rich colour in good trusses, also flowers in April.

Earl of Athlone.—Probably the best hardy deep red yet raised, but still a trifle expensive, as it has only been introduced a few years.

BRIGHT REDS.

Bagshot Ruby.—Flowers in May, a great favourite.

B. de Bruin.—Another old favourite, also flowers in May and June.

Britannia—A new Dutch hybrid of great brilliance, in large trusses.

Broughtonii.—Flowers in April, a very old arboreum hybrid with a good deal of rose in the colour; grows to a large size.

Doncaster.—One of the best; does not fade in the brightest sun.

Essex Scarlet.—Close and rather tight trusses, but a fine clear colour in May.

UNWIN'S GOLD MEDAL GLADIOLI

Our 1925 Awards at six of the leading Shows were: Six Gold Medals and one Silver Cup. We offer the very best and most distinct English, American and Dutch Novelties and standard varieties at "*buyable*" prices.

LARGE FLOWERING VARIETIES.

Splendid, stately and majestic flowers in a wonderful range of colours and colour blendings. One of the most noble and striking of all garden subjects. Adaptable, easy to grow and inexpensive. Don't be without them this season.

R. Smithii aureum, yellow, 1-1½ft. .. .. 2/- each, 18/- doz.

R. Jacksonii, light crimson, very early, dwarf grower, 1ft. .. .. 3/- each, 30/- doz.

Azalea amœna, beautiful purple crimson, 1-1½ft.

A very large collection of Himalayan and Chinese species grown.

CATALOGUE ON APPLICATION.

H. WHITE

Sunningdale Nurseries

WINDLESHAM II SURREY

(Late NOBLE'S. Established 1847.)

Telegrams—WINDLESHAM. *Telephone*—44 BAGSHOT

Unknown Warrior.—Very fine large trusses; size of flower and leaf depends on a certain amount of shade.

PINKS.

Corona.—Excessively floriferous, with good large trusses in varying shades of soft rose and pink; inclined to fade in full sun, but even the colour to which it fades is pretty.

Cynthia.—A rose that hovers on the crimson; might be included under bright reds. May and June.

George Hardy.—Large trusses of pink fading to white; flowers in April and early May.

Lady Clementina Mitford.—Peach-coloured; an uncommon shade.

Lady Eleanor Cathcart.—A good clear rose spotted with crimson. Flowers carried abundantly in smallish trusses in May.

Mrs. E. C. Stirling.—Would be magenta if deeper in tone, but is so pale that it is most attractive.

Pink Pearl.—One of the best known of all hybrids.

WHITES.

Duchess of Portland.—One of the best of all whites, large foliage and a large truss. Corolla faintly tinged with yellow. Flowers in May and June.

Gomer Waterer.—White flushed with pink.

Helen Schiffner.—An old white with smallish trusses carried in May.

Loder's White is the best hardy white hybrid, enormous flowers carried in fairly loose trusses, and so does not look crowded. Is best in partial shade.

Mrs. A. Waterer.—White with a yellow eye, in tight trusses.

Mrs. Lionel de Rothschild.—A fine large-trussed white with a crimson blotch.

The Bride has green markings and a small truss, but is included for its great free-flowering qualities.

PURPLES AND MAUVES.

Fastuosum flore pleno.—Popular with those who like double flowers; a deep mauve in May

Purple Splendour is the best rhododendron of a real purple colour.

YELLOWS.

Cunningham's Sulphur.—A good yellow and low growing; coming into cultivation again.

Smithii aureum.—Large trusses of rather a washy yellow, but yellows are rare.

CATALOGUES RECEIVED.

Messrs. Maxwell and Beale, Broadstone, Dorset.—Plants for rock and alpine gardens, moraines and herbaceous borders. Also a comprehensive list of hardy heathers which all lovers of heaths should procure.

Messrs. Perry, Hardy Plant Farm, Enfield.—Hardy plants for the water garden, with several fine illustrations. Also an extensive selection of all hardy plants.

Mr. J. W. Forsyth, Cyclamen Grower, Putteridge.—A list of cyclamen of the Caledonian Strain, and early flowering chrysanthemums.

Messrs. Barr and Sons, Covent Garden.—List of hardy perennials, including rock plants, alpines, hardy climbers and wall shrubs.

Messrs. J. Stormonth and Son, Kirkbride, Cumberland.—A well illustrated list of rock and border plants. There is a wide selection offered and all rock garden enthusiasts would do well to write for this catalogue.

Messrs. Sutton and Sons, Reading.—A supplement to their seed catalogue, which deals solely with garden equipment. This handy brochure is well illustrated and will be found exceedingly useful to have as a reference book.

Messrs. James and Geo. H. Matthews, Harold Wood, Essex.—A list of vegetable and flower seeds.

Messrs. Knights, Wolverhampton. — A handy and useful little booklet on the upkeep of lawns, greens and tennis courts, which all amateurs would find of great assistance. Price 6d.

SALE OF ROSES

At 33⅓ per cent. less than catalogue prices.

HAVING so far sold our stock of Roses that the catalogue is no longer a reliable source of selection and not having enough each of different kinds to justify advertising the balance in named collections, we are offering what remains of our stock of bush, standard and climbing Roses in carriage paid quantities in varieties of our selection, at 33⅓ % less than list prices.

The varieties are all first-class (not an obsolete one among them), the trees are excellent and, while all buyers will get remarkably good value for money, the first comers will have the advantage of newer and more expensive varieties for as long as stocks last.

WAKELEY'S *Celebrated* Hop Manure

(PATENTED)

THE ORIGINAL AND ONLY RELIABLE SUBSTITUTE FOR STABLE MANURE

DIPLOMA AND MEDAL, ROYAL INTERNATIONAL HORTICULTURAL EXHIBITION, 1912

DO YOU REALISE IT?

A large bag of WAKELEY'S PATENTED HOP MANURE at a cost of only 7/- carriage paid to your door (if within 25 miles radius of London, or at a trifling extra if beyond), GOES AS FAR AS A CART-LOAD OF STABLE MANURE, without any of the defects of the latter; gives better results, is easy and clean to use.

Every ounce of Wakeley's Hop Manure is of value to the soil, supplying the necessary HUMUS in addition to the valuable plant food. Worthless rubbish is not added to make weight (as is the case of some artificial manures advertised).

Thousands do realise it, the proof of this is the constant flow of UNSOLICITED LETTERS received from time to time in praise of the wonderful results obtained at such a moderate cost (see Booklet for selection).

BEWARE OF IMITATIONS.—Genuine Only in our Marked Bags containing Guaranteed Analysis.

ILLUSTRATED CATALOGUE giving full particulars and testimonials sent on receipt of post card.

CASH PRICES (including bags):

Small (about 1 bushel)	3/-
Large (about 4 bushels)	7/-

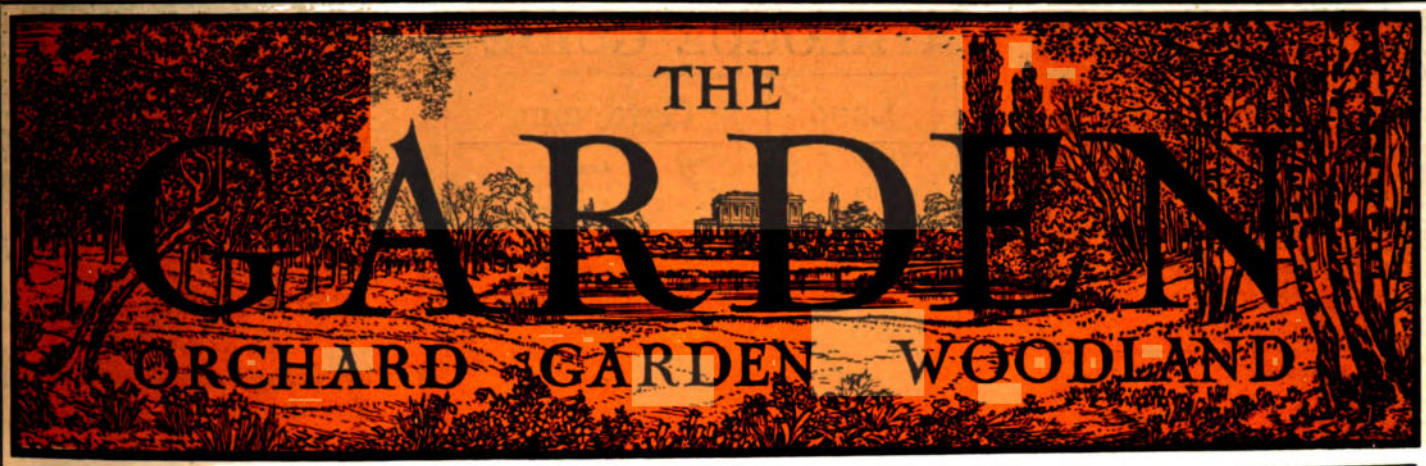
APR 12 1926



Vol. XC.—No. 2837 Saturday, April 3rd, 1926 Price THREEPENCE

TWO BEAUTIFUL NEW PLANTS

FOR MARCH AND APRIL PLANTING

MICHAELMAS DAISY BARR'S PINK.

THE FINEST PINK MICHAELMAS DAISY YET RAISED.

Excellent as a cut flower, remaining open and lasting well in water; equally charming in artificial light as in daylight.

"Until lately one had to exercise a certain amount of imagination with the pink Michaelmas Daisies, but now the pinks are really and truly pink, and of the newest varieties none is more prominent than Barr's Pink, which, with great beauty of rich colouring, combines a graceful habit, and one recognises that in this Messrs. Barr & Sons of Covent Garden have raised a variety that will long continue in the front rank of hardy flowers."—COUNTRY LIFE, Oct. 10th, 1925.

Strong plants .. .. .. per doz. **36/-**; each **3/6**

SCHIZOSTYLIS, "Mrs. Hegarty."

(NEW PINK CAFFRE LILY). This beautiful NOVELTY was shown before the Floral Committee of the ROYAL HORTICULTURAL SOCIETY on October 18th, 1921, and was at once given an AWARD OF MERIT. The flowers are of a beautiful satiny rose-pink, and keep on opening out in succession for a very long time. The general habit of growth is that of *S. coccinea*; it is as hardy and requires the same treatment.

A charming pot-plant .. .. per doz. **12/6**; each **1/3**

BARR & SONS, 11, 12 & 13, KING STREET, COVENT GARDEN, LONDON, W.C.2.

Garden Supplies, Ltd., Cranmer St. Liverpool

ALPINE PLANTS, BORDER PLANTS, CHOICE FLOWERING SHRUBS, MINIATURE CONIFERS, HARDY HEATHS, HARDY FERNS, CLIMBERS. One of the oldest, and perhaps the finest, all-round collection in the country.

We grow some 4,000 kinds of all the best outdoor garden subjects, including such items as 100 kinds of Michaelmas Daisies, 100 kinds of Campanulas, 50 kinds of Hellebores, 200 kinds of Saxifrages, etc.

Our Catalogue of these is beautifully illustrated, shows how to build a rock wall and water lily pool, and tells about soils, etc., etc. It makes a fine reference book on plants. It is sent post free for 1s. which may be deducted from orders.

KIRKBRIDE, by CARLISLE.

KILL those WEEDS!

HOEING & HAND-PICKING OF WEEDS ARE BACK-ACHING, TEMPER-TRYING JOBS.

WHY NOT SAVE TIME & TROUBLE BY CLEANING THE PATHS WITH

COOPER'S Weedicide

("Highly Commended" by the Royal Horticultural Society)

1 gallon of Weedicide (price 9/-) dilutes to 100 gallons water; the cost of the ready-for-use mixture is, therefore, about 1d. per gallon, and is sufficient for treating 300 to 400 square yards.

1 pint 1/9 1 quart 3/- ½ gallon 5/- 2 gallons 17/- 5 gallons 36/6

IF YOU PREFER TO USE A NON-ARSENICAL WEEDKILLER, WE RECOMMEND

McDOUGALL'S PERFECT SAFETY WEEDKILLER

Involves no danger of poisoning to Domestic Animals, Poultry, Game, etc.

1 pint 1/6 1 quart 2/6 ½ gallon 4/- 1 gallon 6/6 5 gallons 25/-

Write for our Illustrated Leaflet, "THE WEED PROBLEM SOLVED" and you will learn how weeds can be eradicated quickly and easily.

If unable to obtain these Weedkillers locally, please write :—

COOPER, McDOUGALL & ROBERTSON, Ltd.,
BERKHAMSTED, Herts. 1469

APRIL PLANTING

There are many shrubs and plants which may be successfully planted during this month.

EVERGREENS such as Hollies, Yews, Bays, Laurels, Thuya Lobbii, Cupressus and other Shrubs.
CLIMBING PLANTS in pots, including Climbing Roses.
HARDY PERENNIALS and ALPINE PLANTS.
HARDY CHRYSANTHEMUMS. VIOLAS.

We grow large quantities of shrubs in pots such as Cupressus, Escallonias, Veronicas, Rosemary, Choisyas, Fuchsias, etc., for planting at any season.

Catalogue and Special Spring List on application.

THE BARNHAM NURSERIES LTD. - BARNHAM, SUSSEX

Berberis Darwinii and stenophylla.

(DAISY HILL HYBRIDS.)

		each.	
Darwinii macrophylla		1/6	2/6
" pendula		2/6	3/6
" prostrata		2/6	3/6
Stenophylla autumnalis, flowers in autumn as well as spring		3/6	5/-
" coccinea, scarlet flower buds		3/6	5/-
" compacta, cushion habit		2/6	3/6
" corallina compacta, the gem of the series		3/6	5/-
" diversifolia, most profuse flowering		2/6	3/6
" gracilis, charming habit		2/6	3/6
" " nana, a miniature of the latter		2/6	3/6
" irwinii, a well known and profuse variety		2/6	3/6
" latifolia, the most robust		2/6	3/6
" reflexa, very distinct		2/6	3/6
" semperflorens, an ideal Rock Garden shrub, in flower for eight months of the year		3/6	5/-

All the above are Daisy Hill production and are offered as own rooted plants.

Full descriptions will be found in Tree and Shrub List, free on application.

KILLALOE :: Co. CLARE

"Mine are five weeks early"

"—and I know why, too. It's because I make *sure* that they have plenty of sunshine. . . . How? Why, by trapping all the sunshine they get with the Chase Continuous Cloche. It keeps young plants always warm and snug whatever the weather. Keeps the ground moist, too—there's hardly any hoeing to do, and all watering can be done without once removing the cloche. The water soaks right to the roots from outside—which is one reason why the ground never cakes. That's much more convenient than the old-fashioned frame that has to be perpetually opened and shut. Besides, as you get no shadows at all, there's no unnatural 'drawing up.' And the ventilation's splendid—the Chase Continuous Cloche doesn't coddle, I can tell you. Why, look how sturdy these early plants are. . . ."

With the Chase Continuous Cloche you can make sure of having big, fine vegetables ready weeks before the usual time—and save time, trouble and seeds as well. It gives complete protection from frost, birds, animals and excessive rain.

For general use, order "A" PATTERN, 7 in. high; box of 12, enough for 14 ft., **18/-**; 24, **35/-**; 52, **55/-** For fairly large plants, "B" PATTERN, 9 in. high; set of 15, enough for 22½ ft., **35/-**; 30, **60/-**.

Write for full particulars.

A Prolific Garden

cannot be maintained without the aid of some kind of manure. Stable manure is now scarce, and is bulky to cart and spread on the land. No artificial will altogether take the place of natural manure, but a good well-balanced fertiliser, used during the growing season, is a wonderful aid in producing high-class garden crops. No fertiliser is cleaner, more effective, or economical than

PEARSON'S CHEMICAL MANURE

which is compounded from the purest chemicals. It contains every element necessary to plant life which is not present in any ordinary garden soil. A glance at the analysis will prove that this manure is as cheap as any on the market, while nothing can beat it in ease of application and results.

THE VALUE OF CORRESPONDENCE

WITHIN the last three months a large number of letters of appreciation of THE GARDEN have been sent in from interested readers. A natural and becoming modesty has kept us from printing them, but it is pleasant to learn that THE GARDEN is appreciated by every kind and condition of gardener. There is one letter, however, that appeared in the issue of March 6th, from which I shall quote. The correspondent writes about a form of Hydrangea hortensis and says, "His letter, coming as it does from overseas, is an instance of the friendly interest which exists among readers of THE GARDEN. I have further proof of this, for my query brought me some very interesting correspondence. . . ." Now, this friendly feeling is what we wish to encourage, for, as I have remarked before, there is no profession or hobby like horticulture for showing a willing *camaraderie* among its members. The only complaint that I have to make is that all answers might have been sent to the paper, for doubtless other readers have been interested in this correspondence. That is our point: that most correspondents are satisfied with the replies given by readers of the paper. We should like this section to increase in value, and are always willing to help readers to trace plants that are difficult to find through ordinary channels, and by ordinary channels I mean the nurserymen and seedsmen's catalogues. There is no doubt that many fine old plants that are now forgotten except in some cottage gardens would be worth reintroducing into popularity again.

It is just as true that many people do not realise the possibilities of the Correspondence columns. To give an instance: A reader wrote and said that he did not approve of the selection of varieties of a herbaceous plant given in one of our articles. He said that he found that others were far better, and left it at that. He mentioned none by name. Everybody is entitled to their own personal opinions, and the author of the article in question was only giving a suggested list, not laying down the law. It would have been instructive to have had our correspondent's alternative list, and it would certainly have been printed. If he felt so strongly that he could better our contributor's suggestions, he should have sent in his own ideas. The purpose of THE GARDEN is not to be dogmatic and say that such a thing must be so because it is mentioned in the paper. Its purpose, as I have said before, is a clearing house of horticultural information. Many times has a little healthy argument in our columns helped to clear up some difficult point about a plant or some peculiarity of cultivation. It is by such means that the friendly interest which exists among readers of THE GARDEN is fostered. No one who has the real horticultural spirit should mind criticism as long as it is constructive. As long as the correct information is disseminated it is all that matters, for correct information should be everybody's property.

PECULIARITIES OF THIS SPRING

This odd season has produced many curious anomalies in the flowering of plants. A week ago R. lacteum was almost over in a garden in Berkshire, while R. præcox was hardly in full bloom; the opposite was the case in another garden in Hampshire. At Kew last week tulips that were just showing colour on April 12th of last year were nearly out. What has happened is that, whereas January and February flowers have kept their proper season, or were even a trifle late, those whose normal flowering time is April have become precocious and have been forced into untimely growth and flower. Consequently, many plants whose normal times of flowering are a month or six weeks apart are to be seen in flower at the same time. This is a rare occurrence and not one to be encouraged, for, if the present cold spell increases, there is bound to be damage, at least in the south. In any case, the immense show of bloom this spring is glorious; prunus, magnolia, stachyurus, forsythia, rhododendrons are making as fine a show as they have ever done, a sign that they have liked the hard winter and responded to the consequent ripening of their wood. It will be noticed that shrubs planted in fairly open positions are flowering particularly well, owing to their unusual ripening, a sign that the freest circulation of air around them is often beneficial. From every part of the country come reports of the promise of the coming season as one particularly favourable to gardening, so long as the weather is kind to us On the other hand, to be really pessimistic, it is just at such promising times that we are usually favoured with a May blizzard: the weather has been so peculiar up to the present that there is no reason to hope for an immediate normality. All we can do is to hope for the best and be suspicious enough of our climate's intentions to be ready to rush out in the middle of a snowstorm to render first aid to some particular favourite in our gardens.

ANNUAL COMPOSITES in the GARDEN

THERE is a subtle fascination to many of us connected with the composite flowers. In the earliest days of childhood, long before the hows, whys and wherefores of plant life or the problems of cultivation trouble the infantile mind, the flower of all flowers is the humble daisy—the commonest of our native flowers and the most perfect example of its Natural Order. After a few short years, when the daisy-chain-maker has developed into a young student of botany, he appreciates the inspiration of that earlier botanist who gave this easiest of all families of flowers to distinguish the sound, descriptive name of compositæ.

It is interesting to recollect that while it is a perennial composite that is the family's commonest representative, it is the annuals that are the most numerous hardy garden plants, and at the moment, when the planting of the longer lived trees and shrubs and herbaceous perennials is, or should be, finished for the time, the sowing and growing of annuals are of most importance.

For the most part the annual composites are plants which may well be sown directly out of doors, where they are to flower. Their value is great for such purposes as temporarily filling up the hardy flower border which has recently been newly made or has been overhauled, for the majority of the annual composites have the great merit of flowering freely unaccompanied by too luxuriant foliage, so that there need be no vacant places around and between the groups of permanent plants.

In the background where tall plants are required, one would sow seeds of such composites as the annual sunflowers and would include in addition to the giants, which produce huge golden plaques of flowers, some of the newer varieties, such as Wine and Primrose, which gives an uncommon combination of claret and deep primrose shades. In contrast to the tall single sunflowers, there are the large doubles, Sun's Eye and Californian, which produce bold rosettes of rich colouring. Even though the plants did not produce many flowers, the cosmeas would be valuable for their graceful foliage. The newer varieties which are catalogued by the leading seedsmen are rather dwarfer in habit and flower much earlier in the summer. By mid-August the graceful spreading plants are spangled with lovely composite flowers of purple, pink, mauve and rose shades.

For the middle portion of the border the choice of suitable composites is much wider and often there will be found sufficient space to grow seedling dahlias and Japanese chrysanthemums. The possibilities of these plants as annuals were splendidly illustrated by Messrs. Sutton and Sons last year at the fortnightly shows at Vincent Square. Although these attractive exhibits were mostly composed of delightful flowers from seeds sown out of doors, it is wiser in the private garden to sow the seeds in gentle heat and plant out the seedlings towards the end of May. The tallest of the everlastings, the helichrysums, have an especial value in their shining, globular flowers of so many beautiful colours. The newer zinnias also have particular colour value, for the middle of the herbaceous border. The colours have been improved and in several strains the plants are also improved in habit. The best results are obtained when the seeds are sown in heat early in April and the plants set out towards the end of May in fairly rich soil. Where this method is not practicable, very good plants may be raised by sowing *in situ* under a hand-glass during the middle of April.

Although they are of perennial habit, it is found necessary in many gardens to treat the best of gorgeous gaillardias as annuals and they are well worth procuring and planting annually. Apart from the beautiful named varieties which are raised from root-cuttings, good showy flowers may be obtained from seeds sown early in the season. The gaillardias are best grown towards

A LARGE-FLOWERED DOUBLE ANNUAL SUNFLOWER.

HELICHRYSUMS ARE THE TALLEST OF THE EVERLASTING FLOWERS AND ARE USEFUL IN THE BORDER.

Digitized by Google

the front of the border and for similar positions there are the delicious sweet sultans, coreopsis, cornflowers, marigolds, sweet scabious and the annual varieties of dimorphotheca. The last named are sun-loving plants in their own country, but if the soil is well drained they seem to bloom equally well with us and over a long period in wet seasons. The sweet sultans should not be sown in a hot and dry position, as under those conditions the flowers are very liable to be infested with insects.

The true annual chrysanthemums are composites which produce flowers of great charm over a long period. The varieties known as Morning Star, Evening Star and Northern Star are excellent. As a neat, edging plant or as a groundwork for taller subjects, no other composite is so floriferous or is more valuable than the dwarf ageratum. The seeds should be sown in gentle heat to obtain good results.

The value of the annual composites for furnishing a regular supply of cut flowers is as great as in the flower border. The most suitable kinds include sweet sultans, calliopsis (coreopsis), cornflowers, sweet scabious, marigolds, annual chrysanthemums, helichrysums, cosmeas and gaillardias. A. C. B.

CAPRICIOUS PLANTS

SINCE we have had this little garden I tried in vain to grow herbaceous phloxes till a fit of impatience led to wonderful results. I could not blame the soils I used. Clay is the foundation soil here, and in it I have dug and trenched and dug again. Every time we go out in the car I sneak a sack, basket and trowel into it inside an old rug. It has got to be done that way, because the bored look that crept over my husband's face when I did it openly was really painful to look upon, and the main business of a home-maker is to avoid an atmosphere of boredom. I was lucky to come across a few loads of tennis ground turves which had been lying piled up for a year. The groundsman named a stiff price, but the garden was crying out for such and I mentally decided what I could do without in the way of new apparel. My birthday brought a gift of two tons of river sand and my Christmas cheque is already condemned for plants already obtained. So with sand, fibrous loam, leaf-mould and such like, I have no excuse. Yet, I ordered phloxes by the dozen and followed the instructions sent by each nurseryman with his special bundle of plants, all with the same result—death. My last lot had very special attention—I lifted them before the fatal season, potted them up and plunged them in sand in a cold frame. They were planted out, looking very healthy, in early spring. Near the flowering season, though mulched with oak-leaf mould and kept moist, they began to look miserable. Now, in one corner of the garden I had a large pile of broken up asphalt path—the ground under it was sodden clay—so I added beech hedge clippings, grass roots and any refuse that would not throw seeds to make a foundation for another bed.

One morning I went to inspect my group of phloxes. Some domestic arrangement had ruffled my temper. I grimly dug those phloxes up and threw them on the rubbish heap, saying that at least they would make a foundation for more grateful plants.

We went to the moors for some weeks, when I returned I had to tackle a herbaceous border, dig it out, lighten up the soil, and replant. This kept me going all the winter in my spare time, because there were a great many house-bulbs to see to. Spring came. One morning I thought I would begin to get the asphalt heap sorted up. There were my phloxes, strong and happy, the perverse things! they were in their element. This brought to mind that when I first made this garden, it was done in groups of colours, somehow a lilac phlox got in among the blue colours. It was looking miserable, too, so I carried it on a spade and left it high and dry all one winter, forgotten, on a small heap of gravel. Next spring, healthy shoots came up, so I just threw some soil round the roots and the plant flowered well. The colour was not good, washed out; it was a poor type, so I threw it away. No more pudding mixtures of rotted leaf-mould, sand and loam for my phloxes.

AQUILEGIA GLANDULOSA, OR THE BLUE SIBERIAN COLUMBINE.

Aquilegia glandulosa led me a dance, too. I brought one little plant back from Clarence Elliott's garden at Stevenage with a collection of "try its." That little aquilegia dwindled away and died: I watched the little green bud in the centre, but one day something ate that. I dug the plant up and found that no fresh growth had been made. So I ordered half a dozen and planted them in pairs. The tennis lawn sods were by that time a delightful border, so one pair was planted at the end of it; the second couple went into a border which was well mixed with smashed-up flower pots, potting soil and old black soil from a garden where we were extending some house property, the third was planted in a border of yellow loam led from the side of a beck, supposed to be the top spit, but I "hae me doots." The first pair won easily, the second grew, but not heartily, the third seemed to attract all the little worms to sleep at the roots while their mothers (the worms) came to the surface for leaves to aerate that pretty heavy soil. I dug these four aquilegias up, washed the roots gently and placed them in sanded holes near the winners.

There was a time when I tried the oft-given advice to leave plants alone. That cannot be done on this north-east coast. I have gone back to some of the methods I used as a child. In those impressionable days a hospital nurse told me that the first thing that happened to a patient on entering the hospital was to get a bath. Now, when I see a plant miffing off, it is dug up, roots inspected and swished in barely lukewarm water or else left in a moist bed of sand for a bit. A double lilac primrose resented its removal from Ireland (I don't wonder,

Digitized by Google

to a district like this). It had many rides round on the trowel to different quarters and soils, till I chopped it up and planted the bits in the new border. A healthy group of young primroses has now come up.

Last summer at a meeting of some biological students in Edinburgh Botanic Garden, we were taken to the propagating frames. The demonstrator showed us how cuttings were just stripped and inserted in moist sand, pulled up at intervals without ceremony to see if they had struck and were just put back again to go on with their work. Another habit of our youth!

Two plants, Buddleia alternifolia and Dracocephalum Isabellæ (what a name, I did not realise till I was transplanting, that I was dealing with a sage), have not flowered with me. This is their second year, so perhaps I am impatient. I transplanted the buddleia last spring into newly made quarters and splendid growth has been made. I have staked it round with beech branches for the winter. It ought to bloom next year. I was held spellbound by this buddleia in the Edinburgh Botanic Garden. It was a welcome change of conversation, too. I had just rashly asserted that I did not like rhododendrons, would not grow them and really did not want to see any. I was politely but dryly asked if I knew anything about them. I had not seen the gardens for some years and made this statement just as I was going to see all the alterations.

I am not prepared to love any of the large types yet, but the dwarfs intrigued me. In a new border just behind the rock garden was a group of beautifully shaped tiny rhododendrons; they were not in flower. I grow six dwarfs now and hope to meet many more as my knowledge increases. Servant maids often refuse to eat venison, hare, macaroni and cheese, simply because they are not used to such fare. It is just custom and use. When we run down a fashion, no matter if it be in plants, animals, or hats, we should pause to remember that a closer acquaintance might change our opinion.

Dracocephalum Isabellæ came up last spring after all, for I thought the winter had killed it. It did not flower. I have removed it over to the new garden where the lawn was, into fibrous loam and sand and leaf-mould with freestone chips freely scattered down through the soil. Two freestone rocks are embedded so as to shelter it as well as Veronica Hulkeana and Cistus formosus. Bracken is packed about this trio and held in place by beech twigs. At the end of the sage branches I see purple blobs, I wonder if these are the future flowers! As the plant seems to die back in winter, what is to be done? FLORA DYSART.

SOME BEAUTIFUL SHRUBBY VERONICAS

WHEN making a selection from among the almost innumerable flowering and ornamental shrubs available at the present time, the merits of the subject of this brief article should on no account be overlooked. A variety of shrubs recently introduced from China and elsewhere are nowadays being offered in ever-increasing numbers, and while many of these are unquestionably of great value, the shrubby veronicas hailing from New Zealand should receive a fair share of consideration, as they are ornamental whether in flower or out of it, and some or other of the many varieties are in bloom from early summer until the frost cuts short their efforts; in fact, at the beginning of last December flowers were still showing, and that after a spell of fairly severe frost and generally cold weather experienced at that time.

Veronicas offer no difficulty with regard to cultivation, and even when cut severely back by a hard frost they, in most cases, break away freely again—in this garden some good plants of Andersonii variegata and other varieties were practically given up as lost a couple of winters ago after some heavy black frosts—but they, with few exceptions, broke away again and are to-day as fine as ever. Of course, I do not mean by this that veronicas should be planted in exposed positions, except perhaps the very hardy Blue Gem, but merely wish to point out that from our own experience they are reasonably hardy and can stand a fair amount of severe weather.

For the front of shrubbery borders some of the dwarfer and more compact hybrids can be recommended, while farther back and in situations where they will have room to develop varieties such as Reine de Blanc and Veitchii may be planted to advantage. The following varieties are all worth growing, and, judging from results in this garden situated in the north of Ireland, they are not unduly fastidious as to soil and are reasonably hardy.

GAUNTLETTII.—This is one of my favourite varieties, a neat, compact grower and very free-flowering from late summer until frost intervenes. The flower-spikes are a very attractive shade of deep pink, and are always certain to attract attention even in a large collection.

REDRUTH.—Another compact-growing veronica with darker foliage than the preceding, bearing large spikes of bright crimson flowers. A really striking variety.

LA FAVOURITE.—A very fine deep purple with glossy crimson shaded dark green foliage that always looks fresh and cheerful.

VEITCHII.—This is a coarser-growing and more vigorous veronica which requires a greater amount of room than those previously mentioned. It is, nevertheless, a handsome variety and bears very large flower-spikes of a bright, almost sapphire blue colour that is very attractive. The flowers are produced as long as frost will permit, but it may be rather more susceptible to "Jack" than some of the others, as it grows very freely and the young shoots are rather soft. It is still flowering here, however, and that, as previously stated, after a pretty severe spell of hard weather.

REINE DE BLANC.—An exceedingly vigorous and early-flowering white that helps to extend the flower season by coming into bloom quite early in the summer. This is much the hardiest of those noted so far, and does extremely well in places overhung by tall trees where few other dwarf shrubs would succeed. The flower-spikes are long and very freely produced, while the plant should be given plenty of room in which to develop.

ANDERSONII.—A vigorous grower with large spikes of lilac-coloured flowers. It is very effective, but not so refined as most of the others, and I much prefer the variegated form, Andersonii variegata, which is a very ornamental shrub and makes a most attractive subject for the front of a shrubbery. It is reasonably hardy and even if cut back by frost breaks away freely again, and in late summer the large lilac flowers are freely produced. The foliage is soft green variegated with creamy yellow.

TRICOLOUR.—This is another handsome variegated variety with warmer coloured foliage than the preceding, being shaded with a purplish crimson. The flowers are deep purple red and contrast well with the beautiful leaves.

BLUE GEM, as already mentioned, is hardier, and while, in the writer's opinion, not nearly so attractive as the others, it is, nevertheless, showy and may be planted in exposed situations. It is becoming almost too common and is very largely employed in seaside gardens.

AUTUMN GLORY is a violet-coloured variety with small flowers and foliage, the latter being a dark green. It also is hardy and makes a good show when in full flower.

The above varieties, of course, are only a very small selection out of the many available, but they are sufficient to show those who have not grown them what a wide range in form and colour is available among the shrubby veronicas. It would only be tedious further to enumerate varieties, but before closing I should like to mention one of the dwarf shrubby forms, namely, Veronica Lyallii, a beautiful and free-flowering little shrub covered in summer with small pale mauve white flowers with dark eyes—a very attractive plant for rock garden or border.

Most nurseries specialising in shrubs offer a good selection of veronicas, but with so many sorts available it would be practically impossible for any one firm to offer all. However, with few exceptions, good plants of the above should be easy to obtain. Tricolour and Gauntlettii do not seem to be generally offered, but good plants of them may be obtained from one or two nurseries. CECIL M. BAILEY.

A WATER LILY POND

A SHEET of water in the pleasure grounds or park adds very considerably to the beauty of the landscape. It also provides scope for the planter to adorn the surface with irregular groups and masses of water lilies, and the margins round the pond with suitable trees and moisture loving shrubs and plants.

Water lilies succeed best in still water. When planted by the sides of a running stream one must construct creeks or basins, protected by large boulders. These form practically still pools for the plants.

When considering the construction of an artificial pond or tank a choice is often between one distinctly formal in outline to fit the rigid lines of the surroundings, or one as natural as possible, so as to appear part of the landscape. Obviously, this will be in a low-lying part of the grounds to save labour in excavating. The accompanying illustrations are of a water lily pond at Kew that is a very good example of an artificial piece of water in natural surroundings.

In the construction of an artificial tank or pond the question of providing a water-tight bottom and sides is important. Whether clay or bricks and concrete is used will to some extent depend on the local conditions and the position. I am of the opinion that the water lilies thrive better in a clay-lined sheet of water. It is certainly easier to keep clean, and cheaper to construct, unless clay is very difficult to obtain. For obvious reasons bricks and concrete are generally employed in the making of a formal tank or basin to be in keeping with formal surroundings.

Do not stint the use of clay for puddling in the original construction. A depth of 1ft. all over the bottom is not too much, particularly if the natural soil is light and gravelly. The thickness of the clay forming the sides may slope up from 1ft. at the bottom to 6ins. or 8ins. at the top, but here again err on the side of plenty, as a little will be lost when cleaning in subsequent years.

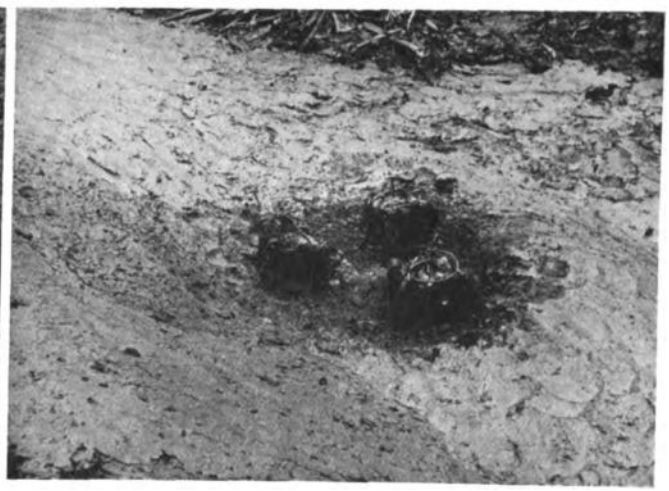
SOIL.

In natural ponds or lakes the soil will probably be suitable for the plants if not too deep, but it is advisable to add some good fibrous loam and a little cow manure to cover the clumps at the outset.

When dealing with artificial water it is another matter. Good material for water lilies consists of fairly heavy top-spit loam from grassland, with a little cow manure incorporated. Whenever possible provide for the emptying of artficial water. It aids so much in the cleaning, and in the planting and re-planting of water lilies.

There is nothing to be gained in crowding the surface of water with plants. Open stretches of water between the groups or clumps add very materially to the charm of the plants in flower and the picture as a whole. In dealing with large areas of water opportunity should be taken to plant a number of groups or a colony of one variety in preference to a general mix-up of sorts in single mounds or baskets. In the latter case the effect cannot be so bold and striking, while there is also the liability of the stronger growers spreading to the positions of the smaller-growing sorts.

THE MOUND IN THE MAKING.



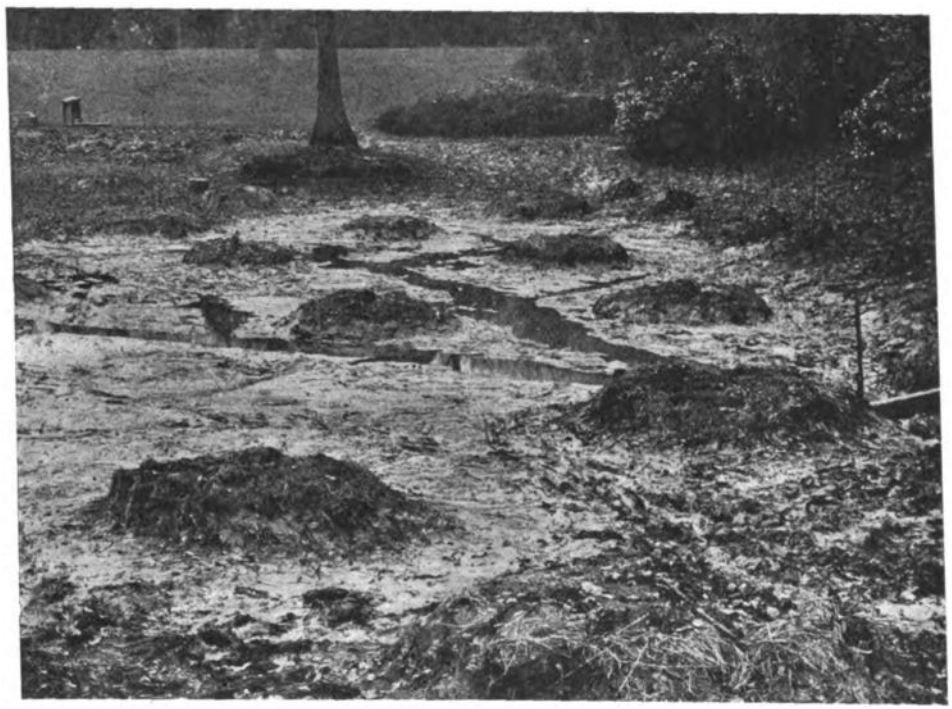
THREE CLUMPS PLACED IN POSITION AFTER PUDDLING.

PROTECTION OF PLANTS AGAINST FROST AND COLD WINDS DURING CLEANING OPERATIONS.

A WELL ESTABLISHED CLUMP, THE RESULT OF CAREFUL PLANTING.

Digitized by Google

The question of planting the roots in mounds of soil formed on the bottom or in baskets is largely a matter of local conditions and convenience. Baskets are obviously desirable when the water cannot be drained off. They provide an easy means of placing the roots in suitable soil and sinking in the water. By the time the wickerwork rots away the lily roots should be safely anchored in the mud at the bottom. Useful baskets for the purpose are the round kind, 1ft. to 1½ft. deep and 3ft. or 4ft. in diameter, used for the transport of trees and shrubs by rail. These will hold sufficient soil to plant three clumps or tufts of water lily roots when divided. Line the inside of the basket with turfy loam and place pieces averaging 1ft. square on the top to hold the nymphæa roots in position and prevent the fine soil in the centre floating away in the water.



A POND DRAINED, SHOWING THE SPACING OF MOUNDS TO PREVENT OVERCROWDING IN THE WATER.

THE DEPTH TO PLANT.

A depth of 18ins. to 2ft. of water above the plants is a useful average for the stronger-growing sorts. Obviously it must vary according to the depth of water in the lake or pond. It is very desirable that the minimum depth of water above the crowns should be not less than 1ft. in the event of hard spells of frosts. The strongest varieties will grow in a depth of 4ft. or 5ft. of water, but this means excessive growth of leaf-stalks and flower-stalks, and should be avoided when circumstances permit the building up of mounds to bring the plants nearer the surface.

All things considered, April is the best time to plant and replant clumps of nymphæas. A little earlier or a week or two later is of no consequence. Do not disturb water lilies when dormant during the winter. The thick fleshy roots are very easily broken, which may cause decay and weakening, if not loss of the plants. Planting is sometimes done as late as June, but in this case the summer will be well advanced before the plants begin to make a show.

During the annual cleaning of lakes and ponds which can be emptied, cover the water lily plants with light litter when likely to be exposed for several days. Cold winds, frosts and hot sunshine in April will soon damage the tender young growths of water lilies when the water is drained off. Should any delay occur in planting nymphæa roots coming to hand from the nurseries, immerse them temporarily in a tub of water or cover with wet moss and mats as a protection from the weather.

The question of cold water or stagnant water and its effect on the growth of water lilies does not arise in the case of natural water fed by springs. When growing in artificial waters it is a mistake to add frequently fresh cold water, as such is liable to chill the plants.

Permanganate of potash is valuable applied to the water once every fortnight during the summer. It keeps the water sweet and prevents the development of the slimy green surface growth called blanket weed. Applied at the rate of about 4 oz. to 2,500 gallons of water it will not harm plants, fish or waterfowl. Either dissolve the potash crystals in an earthenware vessel and spray on the surface of the water between the water lilies or tie in a canvas bag and draw through the water. We often tie the bag at the end of the boat when working over the surface of the pond or lake removing dead leaves from the water lilies, etc.

SELECTION OF VARIETIES.

To be of value to the largest number of readers the following selection of varieties includes the best of the older varieties and a number of the newer introductions. Atropurpurea, crimson purple; Attraction, granite red, tipped with white; *Colossea, rose, changing to a delicate flesh; *Ellisiana, rich currant red with prominent stamens; *Escarboucle, vermilion red; Formosa, rich pink; *Gladstoniana, large pure white flowers with yellow stamens; Gloriosa, carmine red to dark red; Indiana, orange yellow, shaded copper; *James Brydon, rosy crimson; Marliacea albida; M. carnea; M. chromatella, yellow; M. ignea, carmine red; M. rosea and M. rubra-punctata; *Moorei, soft yellow; Mrs. Richmond, violet pink; Newton, rosy vermilion; Picciola, red, carmine and white; Robinsoni, crimson vermilion, lighter centre; Rosita, deep rose, shading to white; Sioux, rich yellow, edged with red; Venusta, flesh pink; and Virginalis, a splendid white.

In forming a limited collection of, say, the best six varieties for a pond I would advise the selection of those marked with an asterisk.

For cultivation in rock pools, tubs and small tanks the following varieties are useful: Laydekeri fulgens, red, and rosea, rosy pink; odorata alba and minor (pumila), starry white flowers; pygmæa alba and Helvola, sulphur yellow.

A. O.

SERVICE FOR READERS

Though so many subjects are dealt with in each issue of THE GARDEN, it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, whether advice is sought as to—

RESTOCKING A GARDEN, COLOUR SCHEMES FOR GARDENS, THE BEST PLANTS FOR CERTAIN SITUATIONS, WHERE TO OBTAIN NEW AND RARE PLANTS, INSECT PESTS, NAMING OF PLANTS, AND THE HUNDRED AND ONE OTHER DETAILS RELATING TO THE GARDEN—

there is always information available from a staff of expert contributors and consultants; *and there is no charge for this.* It is one of the additional means of Service which THE GARDEN is glad to render to its readers.

Also, there is the further convenience which the Service Department affords of supplying readers with data about anything that is advertised in the pages of the paper. Thus, on receipt of an enquiry, particulars will be sent of, say, half a dozen things about which the reader seeks information. The only stipulation is that a stamped addressed envelope shall be sent with the enquiry.

All communications should be addressed to the Service Department, THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C.2.

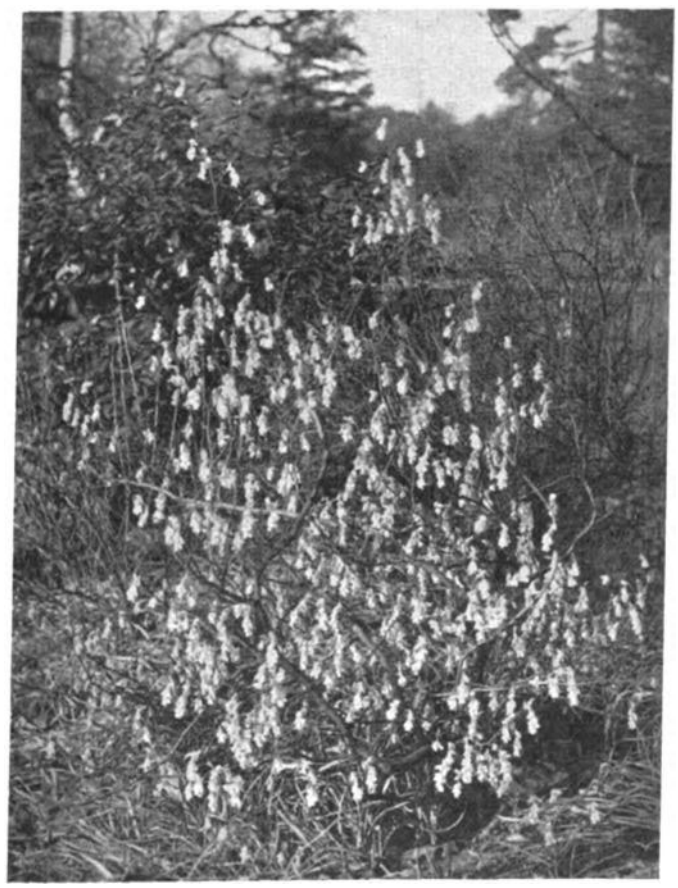
NOTES OF THE WEEK

AN UNCOMMON EARLY-FLOWERING SHRUB.

WHILE walking round Kew Gardens about a fortnight ago I was much struck with the quiet beauty of that graceful shrub Corylopsis spicata, so seldom seen in a private garden. This year its precocity is most marked, being in flower about three weeks before its time. Like many of our other early flowerers, it is a member of the hamamelis family, and like many of them bears flowers of a pure delicate yellow. I wonder if it has struck any readers how strange it is that so many of our spring-flowering subjects have flowers of a yellow tone. There would appear to be a subtle connection between colour and season. To get back to our shrub, it makes a charming acquisition to any shrubbery, and its chief merit lies in its early flowering season. It is a dainty flowerer with rather twining flexible shoots from which dangle the loose spikes of from eight to a dozen flowers. The spike itself shows a fine contrast in colour between the small bell-like flowers with the colour and fragrance of a cowslip, and the greenish yellow bracts in whose axils the flowers are borne. When in leaf the aptitude of its generic name becomes more obvious, as it assumes the general appearance of the common Nut Bush, with its long-stalked, heart-shaped and feather-veined leaves. It is surprising that it is not more extensively grown, as it was introduced by Fortune as far back as 1864. It forms one of the striking examples, and there are many, of a shrub whose beauty—perhaps not outstanding, but nevertheless attractive—has been long overlooked and now deserves to come into its own.—G. T.



CORYLOPSIS SPICATA WITH DELICATE YELLOW FLOWERS.

PYROLAS IN THE ROCK GARDEN.

EVERY botanist knows Pyrola minor, which he has found growing in woods and shady glades where the grass did not grow too luxuriantly. It is not at all a common plant, and so, grown in the rock garden in a moist corner and in shade, it is sure to attract the observant visitor. The flowers are almost white, somewhat like the lily of the valley and borne on a spike some 4ins. to 6ins. high, which rises from the rosette of leaves. Another wintergreen, Pyrola rotundifolia, can be obtained from nurserymen; it is slightly taller than the former, but otherwise very similar. Pyrola uniflora has only one blossom on the stem, a sweet-scented pretty white flower; it, too, is well worth introducing, but the grower must collect it himself, as few, if any, nurserymen stock it—and he may have to travel far, as the plant is seldom found outside the northern pinewoods. All are members of our country's flora, but comparatively unknown to the usual run of gardeners, and therefore worthy of a place. They are rather difficult to transplant, and should be grown in a moist place, in half peat, half loam.—CLYDESDALE.

THE R.H.S. AMATEUR SHOW.

IT would seem that there is quite a possibility of American amateurs competing at the Royal Horticultural Society's Amateur Show, which is to be held at the Society's Hall, Vincent Square, on June 22nd. We understand that Mrs. Edward Harding of Burnley Farm, Plainfield, New Jersey, has written to Sir William Lawrence, Treasurer of the R.H.S., saying that she proposes to enlist the interest of other American amateurs and with their assistance to send over various examples of American floriculture, especially peonies. (It will be remembered that Mrs. Harding, who is well known to the gardening fraternity on both sides of the Atlantic, has presented cups for peony competitions at Vincent Square.) The immense distance which the American exhibits will have to travel does not in any way daunt this enterprising lady, who we understand, has already thought out the problem of transportation and she is optimistic that, with the aid of cold storage, she and her American friends will be able successfully to compete with British amateurs.

ROCK AND STONE EDGED BORDERS.

I AM noticing in suburban, and more particularly in country, districts where new houses are being erected, a disposition to discard the formal edging tiles and divide the path on either side with pieces of stone or rock. In localities where it is not very difficult to procure these—which are really waste pieces or chippings—it is an economical proposition for those erecting or purchasing their own houses, and, incidentally, it gives one the opportunity of making a garden much more attractive than is often the case when blue or red tiles are employed. Some of these roughly constructed edgings are raised above ground level, and thus give one a chance of planting among the stones plants of cushion-like growth, like aubrietias, saxifrages, armerias, lesser-growing campanulas such as carpatica, turbinata and pusilla, besides arabis, helianthemums, cerastiums and various sedums. In niches among the stones one can contrive to put in scillas, chionodoxas, snowdrops, aconites and crocuses, so that, quite early in the year, when once established, these informal edgings become miniature rock gardens that give pleasure for a long time and seldom need to be interfered with.—W. LINDERS LEA.

NARCISSUS EMPEROR.

A NOTE on the behaviour of Narcissus Emperor may be of interest at this season of the year, when spring-flowering bulbous plants are pushing into growth. On one occasion bulbs of this variety were boxed and potted up in the month of October. After being well rooted and top growth sufficiently advanced, the boxes and pots containing the bulbs were brought into heat and gently forced to get early flowers.

When the bulbs had done service indoors they received attention in the way of watering until the foliage died down. Late in autumn—twelve months or more after the bulbs were purchased—they were set out in clumps of eighteen bulbs each on a border which had been recently manured and trenched. The following year not one of the bulbs in the clump under observation produced a flower. But very different were the results the next year, as I counted thirty-three flower buds in April. Yet another clump of eighteen bulbs exhibited thirty-six flower buds at once.

One day I dug down to examine a bulb in one of the clumps, and found that the original bulb had produced three more and each one of these had a flower, making a total of four.—D. A.

BASKETS OF FLOWERING AND FOLIAGE PLANTS.

THERE is always something very attractive about a well furnished and finished hanging basket in a greenhouse or conservatory and the present is an opportune time to prepare them. Quite a number of plants, owing to their straggling, pendulous habits are peculiarly adapted for growing in baskets suspended from a roof. As a general rule it is better to start with young plants—rooted cuttings in March or April—and grow not more than two kinds—(one is better) in the same receptacle. Old plants, as it will be obvious, cannot well be crammed into a limited space, without roots suffering. Among the best and possibly still as popular as any are the ivy-leaved pelargoniums, and fuchsias follow them closely. Some of the long-service varieties of the latter—like Lord Beaconsfield, General Roberts and Rose of Castile—may be instanced. Heliotropes, on account of their sweet perfume, are worth taking in hand, as are also verbenas and petunias. A delightful annual which revels in a warm greenhouse is Thunbergia alata.

Of plants valued for their foliage, Asparagus Sprengeri and Nepeta glechoma variegata are worth consideration.

Fresh green moss should be used for lining the baskets and a compost of loam and leaf-mould provided and firmly pressed in at the time of planting.—W. F.

THE FLAME FLOWER, TROPÆOLUM SPECIOSUM.

An interesting account of success with one of the best of all climbing plants.

THERE are few owners of gardens who, seeing this plant for the first time, do not straightway attempt to grow it. Nor is this strange, considering the charm of its slender stems, delicate green leaves, and soft vermilion flowers. I have no experience of it in Scotland, where it is said to grow so exuberantly; but in Sussex it will completely garland the northern face of a cottage, establish itself in a yew hedge, illuminating both sides (north and south) with trails of blossom in June—and that in heavy soil, with clay beneath. In this garden we had some difficulty with it at first. In preparing the site behind a north wall, we filled a deep, well drained trench with a mixture of peat, loam and sand. The plants—not too good—made only a few miserable growths, showed no desire to climb, and were killed to the ground-line each winter. Others have, apparently, had the same experience, for Mr. Robinson, in the "English Flower Garden," describes the stems as *annual*. Discouraged, but determined to persevere, we top-dressed the ground with rotted hot-bed manure and sand one year, and when the shoots appeared that April, each was given a string to lead it up the wall. No sooner did the leaf-stalks clasp the string than the plant assumed a stronger, bolder growth, which soon arrived at the top of the wall and flowered profusely. Where the stems had clustered, the dead leaves were a sufficient protection and they survived the winter. From that time onward we had no trouble, except to repress it. Now, one never quite knows where it is going to appear next! It has dived under the foundations of the wall and permeates the southern border, where it is allowed to wreathe the commoner shrubs. Behind a dense holly bush it was planted in company with trilliums, ourisias and haberleas, but, disdaining their company and the peat bed, it wandered 33ft. through the bush and, appearing on the other side, claimed a position next to and among a Clematis Jackmani, forming a rich contrast. The holly efficiently protects the stems in winter; if not perennial, they are at least biennial, and break forth into growth at a height of 6ft. to 8ft.: many of these stems had as much as 12ins. of new growth at the beginning of March, and as a natural consequence, they flower early and produce their sapphire-coloured fruits in profusion, adding not a little to the beauty of the plant in late summer.

To those who wish to establish this plant I would say: Obtain really good roots and prepare the site well. Plant in early April, near something that will shade its roots and provide it with something to cling to.—J. COMBER, *Nymans*.

THE FLAME FLOWER ON A YEW HEDGE.

BERBERIS VERNÆ AT THE ARNOLD ARBORETUM.

A BEAUTIFUL BARBERRY.

THE accompanying illustration shows a well developed shrub of Berberis Vernæ *C. Schneider* as it grows in the Arnold Arboretum, Jamaica Plain, Mass. The picture shows the graceful habit of this shrub, but, unfortunately, not the abundance of the pretty yellow flowers, which make it one of the most attractive plants of the Arboretum. Indeed, Prof. Sargent, Director of the Arnold Arboretum, pointed it out to me as one of the best introductions of later years.

B. Vernæ is a native of western Kansu in China; it was first collected at Min-chou, at an elevation of 10,500ft. to 12,000ft., by W. Purdom, and introduced to the Arnold Arboretum. It was described by the dendrologist, C. Schneider, in "Plantæ Wilsonianæ," Vol. III, page 372, in 1913, and named after Miss Verna Berger.

It is a deciduous shrub and perfectly hardy in the Arnold Arboretum, and should do well everywhere in the British Isles. The leaves are clustered, lanceolate, about 1in. long, entire and bright green on both sides. The drooping racemes appear very abundantly, and, although but 1½ins. to 1¾ins. long, are very conspicuous and graceful with their numerous small bright yellow flowers. The berries are said to be red, very numerous and highly coloured, and render the shrub equally attractive later on.

I was very pleased to see this shrub, which was named after my daughter by my friend C. Schneider, when it was in its best towards the end of May.—ALWIN BERGER.

PULMONARIA ANGUSTIFOLIA AZUREA MUNSTEAD VARIETY.

A fine spring-flowering border plant.

THERE is no doubt certain colours of flowers charm us more than others, and those who have not yet grown Pulmonaria angustifolia azurea Munstead variety should add a plant to their collection. It is by no means a fastidious plant to grow and in a few years it will soon form a good sized colony. Some years ago a friend procured a plant for the garden and we had it carefully planted near the front of a south border. Here the situation was somewhat shaded and sheltered, and the border soil inclined to be heavy. In this position the plant soon became established and flowered each year. Last year this lungwort started flowering in the third week of March, while in the middle of April it made a grand display.

The blue tone of this really fine spring flowering plant reminds one of the rich charm colour of Salvia patens flowers. In R. Wallace's Alpine and Hardy Plant Catalogue, this pulmonaria is described as "the true form, uncommon in cultivation, twin heads of flowers each half-an-inch across, and of the palest blue, buds purple, leaves unspotted."

One would like to associate Iris reticulata with this pulmonaria, as its stiff, yet pleasing dark blue flowers are fully expanded when this lungwort is beginning to bloom.

To increase the stock, the large plant was dug up early in October last year and separated in such a way that each portion severed had roots and crowns; then these were notched into one line on another border. While I write these notes—end of February—the young and tender-looking pale greenish red leaves are clasping the compact and clustered round heads of flower buds. The thick roots of this pulmonaria are somewhat

Digitized by Google

dark in colour, while the extremities of some are quite black, and sometimes these black portions are found to be dead.—DAVID ARMSTRONG.

GERANIUM FARRERI.

HAVING had this dainty little plant for two or three years, I suppose one is entitled to consider it successfully established, especially as its career from the first has been in every way satisfactory. Being a very high alpine, we gave it a north aspect with partial shade from the hottest sun, the root-run consisting of gritty loam, leaf-mould and old mortar. It is an entirely herbaceous species, but the growths appear early in spring and the leaves, dull green and something after the style of those of G. argenteum, are followed by a succession of bloom that is maintained pretty well all summer. These blossoms are a good deal larger and open flatter than those of the other species named. They are a very pale shell pink with just a hint of blue to afford them that delicate, evanescent loveliness which is so appealing. Farrer wrote of this geranium producing "runners," but of these we have seen nothing as yet. Indeed, the plant seems to increase so slowly that it would not be easy to detach an offset. The height of the flower-stalks, which rise clear of the foliage, is not more than some 3ins.—A. T. JOHNSON.

THE DAINTY AND FREE FLOWERING GERANIUM FARRERI.

A REMARKABLE WATER PLANT.

ONE of the most interesting of water plants is the Italian eelwort (Vallisneria spiralis), a species which is of easy culture in a tank. The eelwort is a native of southern Europe and grows in still waters. The plant has strap-shaped leaves, and the different sexes are on distinct plants. The eelwort flowers freely during the summer, and it is then easy to observe its remarkable habits. The pistillate or female flowers are borne on long stalks, each of which, while the stigmas are maturing, are enclosed in a kind of bladder. The staminate or male flowers are invested in much the same way, but these grow in thick clusters and one sheath suffices for all the individuals of a cluster. Each of the male flowers is borne on a short stalk which never extends. In the case of the female flowers the stalks lengthen to a considerable extent and finally reach the surface of the water. At this time the floral sheaths of both sexes fall apart and everything is ready for the union. Then a somewhat baffling problem arises. The female flowers held by their long stalks are floating on the surface of the water. On the other hand, the male flowers are fixed far below to the short stalks. In what manner can the sexes be brought together? The difficulty is surmounted in a very wonderful way. At a certain stage in their development the male flowers detach themselves from their stalks and, being lighter than water, rise to the surface. Here they drift about for a while and finally open. At this time the three sepals are twisted back in a most ingenious manner so as to make a little raft. At the same time the two perfect stamens are revealed and these now stand clear of the water like a pair of snail's horns. When, as often happens, the male flower is stranded in the recesses of a female flower, it will adhere to the trilobed stigma and some of the pollen grains are sure to be left. As soon as pollination is an accomplished fact the stalk of the fertilised flower contracts spirally and the ovary is thus conveyed to the muddy bottom, where the development of the seeds takes place.—S. LEONARD BASTIN.

THE PRICKLY THRIFT.

THE number of acantholimons known to botanists is very great, but few of them are in commerce, and of these undoubtedly the best is Acantholimon glumaceum, which has acquired the popular English name of the prickly thrift. It is one of the most distinct of rock plants, and, as its culture is generally easy, there is no reason why it should not be still more largely grown than at present. Yet it has its requirements; the principal of these being a sunny place and a dry soil, with adequate shelter from the coldest draughts of wind in winter. Its native headquarters are on Mount Ararat, so that its needs should not surprise us when we think of the conditions under which it lives at home. Yet it has accommodated itself wonderfully to the conditions of our gardens, and is now a favourite plant with those who cultivate it. It soon forms a large mound of green, spiny leaves, over which are displayed, all the summer, its pretty flowers of a rose pink, the whole constituting a pleasing picture among the rocks and stones of the rock garden. Its main defect with us is an unaccountable habit of dying off, just when we are congratulating ourselves that it will live for many years. Sometimes, too, it develops a bare spot in the centre of the cushion which depreciates its beauty. It is not too easy to propagate, and the best method to adopt is to work some sandy soil among the outer branches and to peg these down into it until they emit roots, when they may be detached. I recommend purchasing plants in pots, rather than from the open ground. —S. ARNOTT.

THE PRICKLY THRIFT IS ONE OF THE MOST DISTINCTIVE OF ROCK PLANTS.

Digitized by Google

FUMIGATION WITH CYANIDE

WHEN potassium cyanide was first introduced to horticulture as a greenhouse fumigant its early champions claimed that it would supplant nicotine and most of the insecticides used in plant houses and vineries; that not only the simple green fly and wood louse would be annihilated, but that red spider and mealy bug were doomed. It was realised and admitted that the gas liberated by combining potassium cyanide and sulphuric acid is of a deadly poisonous nature; but ingenuity had contrived to devise a method by which the operation could be carried out by a person outside the house and therefore beyond the danger zone. It was urged that the immense advantage of clearing glasshouses of all the insect pests which worry plants fully justified the exercise of all necessary care in carrying out what was, after all, no more than a tedious task.

With that contention nobody who has experienced the depredations of red spider and mealy bug can possibly disagree; but it must, nevertheless, be admitted that the new method of dealing with greenhouse pests progressed very slowly for the first few years of its vogue. To attribute this fact to any one cause would be inaccurate, although the enthusiasts sometimes declared that nothing but prejudice hampered the progress of the new and up-to-date fumigant.

It was not long before, in place of potassium cyanide of variable percentage, a double salt of sodium and potassium cyanide came into use which could be guaranteed not only to be far more powerful but consistent in regard to strength and purity; and the vendors also supplied sulphuric acid of a specific gravity.

Another great boon was the invention of a workmanlike apparatus which came on the market as a "cyaniding machine," and with such vastly improved equipment good work became possible. From that time forward cyaniding became increasingly popular in nurseries and the large establishments where indoor plants and crops are produced for market.

Unfortunately, the cyaniding machines were, and still are, expensive, and, except in very large establishments, cyaniding has not been so largely practised in private gardens as might be desired, for it is undoubtedly capable of clearing a greenhouse or vinery of pests which ordinary tobacco or nicotine fumigation cannot shift. The poisonous nature of the gas renders it unfit for use in conservatories attached to dwellings or in small greenhouses standing closely surrounded by inhabited dwellings, but so long as one is satisfied that the interior of a glasshouse may be cyanided without risk of injury to persons or animals outside there is no reason why cyaniding should not be carried on with confidence.

It is quite unnecessary to enter into detail regarding the method of using a cyaniding machine, for the makers provide clear instructions which can only be repeated without amendment. It is well, however, that the operator shall observe certain points of importance in regard to preparations.

First, all ventilators should be closely shut, but left in such a way that they can be opened from outside, for on no account must anyone enter a house while the atmosphere is still charged with fumes.

No vinery or tomato house should be cyanided while ripe fruit hangs. A highly essential point is that the temperature of the house should not exceed 50° Fahr. The atmosphere must be as dry as possible, and no moisture must hang about the foliage of the plants.

The sulphuric acid used is first diluted by mixing with 2½ times its bulk of water: but it is very important that the acid shall be very gently and slowly poured into the water in an earthenware vessel, and that the measurement of the acid and water shall be accurate. If the reverse method is adopted, of pouring water on to sulphuric acid, there is danger of a slight explosion.

The cubic capacity of the interior of the house should be ascertained with precision; but inexperienced users are advised to commence with a moderate fumigation, which may be increased until the maximum is reached should observation indicate that pests have survived the weaker dose, and plants are unharmed.

Assuming that the full strength sodium cyanide is used, the minimum strength may be reckoned at ¾oz. per 1,000 cubic ft. This is usually strong enough to kill aphis and other simple insects. The maximum strength may be reckoned at 1½ oz. per 1,000 cubic ft.; but in dormant vineries and orchard houses a further ¼oz. has been used with safety, and for red spider and mealy bug that strength is sometimes necessary.

One small house may be cyanided by placing the sodium cyanide in a basin and balancing over it a bottle containing the dilute sulphuric acid. A string should be attached to the bottle, looped over a wire, and carried through the keyhole of the door, or through a tiny hole drilled in a convenient spot for the purpose, the motive being to ensure that when the string is pulled from outside the base of the bottle is lifted so that the acid runs into the basin beneath.

The operation should be carried out in the evening; never in broad daylight. Forty-five minutes is the full extent of time the house may remain closed. When opening, hold the breath until well away from the escaping fumes. See that no dog, and certainly no human being enters the house for a few hours after cyaniding.

After several years of research and experiment a new method of cyaniding by means of a powder, without sulphuric acid, has been evolved. Cyanogas Calcium Cyanide is the name given to a preparation which can be used in a much more simple manner, for it is only necessary to scatter the powder evenly along the paths of the greenhouse, and leave it closely shut down all night.

The same gas (Hydrocyanic acid gas) is liberated by thus bringing the powder in contact with the atmosphere and very slight moisture of the paths as is generated by the former method of adding sulphuric acid to sodium cyanide; but the liberation goes on steadily at a very much slower pace over a period of several hours. The same conditions of low temperature and dry foliage are required, but the slowness of action enables the operator to start at the far end of a house, distributing the powder as he walks backwards towards the door, and then shutting it. Next morning open the house wide and wait until all trace of the gas has disappeared before working in the house. A. J. MACSELF.

DAFFODILS at VINCENT SQUARE

THE spring of 1926 must surely stand as a record early-flowering season if one is to judge by the recent displays at the Royal Horticultural Society's Hall at Vincent Square. On the occasion of the last meeting on March 23rd and 24th quite a dazzling blaze of colour met the eye on entering the hall. Yellow provided by numerous exhibits of narcissi was the predominating colour, while the brighter tones were supplied by tulips, hyacinths, shrubs, a fine exhibit of brilliant imantophyllums and alpines. The alpine section had much of interest to show to the rock garden enthusiast, and it was pleasant to note the return of amateur exhibits on a somewhat large scale, reminiscent of pre-war shows.

Daffodil hybridists are working apace, and each year they are raising new varieties which, in many cases, show a marked increase in size and a greater variation in colour when compared with the older kinds. It remains to be seen whether these new introductions have come to stay, for although on the exhibition table they leave nothing to be desired, they may not be good doers and of sufficiently strong constitution to take their place with such excellent all-round varieties as King Alfred. Time will prove whether this is the case or no, but, in spite of this doubt the true daffodil enthusiast will surely hasten to add a few of these choice seedlings to his collection. He will not be able to resist their beauty. Two magnificent narcissi collections came from Ireland, one shown by Mr. J. L. Richardson, and the other by the Donard Nursery Co. The latter firm had some splendid trumpet varieties of immense size and fine substance—Gog and Magog were outstanding. Grenade, Macebearer and March Wind were other noteworthy narcissi. Mr. J. L. Richardson showed a number of excellent novelties, some unfortunately rare at present and consequently expensive. Golden Pedestal, a self yellow incomparabilis of his own raising; Beersheba, a variety showing great development in the white trumpet section; and Glorious, an attractive vigorous poetaz, were a few of the best. There were many other good narcissi, several of which received awards of merit.

Messrs. Barr and Sons exhibited an interesting and varied narcissi exhibit, including many unnamed seedlings. The Leedsii and Barrii types were well represented. Duke of Bedford, a large handsome bicolor trumpet; Crœsus, a showy incomparabilis; and Orange Prince, a poetaz with a yellow

Digitized by Google

perianth and a cup of dark rich orange, were some of their fine and increasingly popular varieties. Pure white trumpet daffodils were much in evidence on Messrs. J. R. Pearson's stand of narcissi blooms cut from home-grown bulbs. Fortune, the rare giant incomparabilis, which created quite a sensation at the time of its introduction, was also exhibited. Messrs. R. H. Bath staged a group of narcissi, including Loud Speaker, a new trumpet variety of unusual size. Prince Umbria was a fine giant Leedsii shown by Mr. J. W. Barr. Narcissi were also shown by Messrs. Cartwright and Goodwin and Messrs. Carter and Co., the latter firm arranging their exhibit in the form of a long grass bank, tightly packed with groups of poetaz narcissi and trumpet daffodils.

The most striking exhibit at the Show was that of imantophyllum shown by Lieutenant-Colonel Sir George Holford. These handsome greenhouse bulbous plants were perfectly grown and the varieties exhibited were particularly brilliant in colour and fine in form. Westonbirt Perfection, Field Marshal, Westonbirt Brilliant and Flame were varieties of the most vivid orange-scarlet. An attractive group of clematis was shown by Messrs. L. R. Russell, particularly flotiferous varieties being President and Nellie Moser.

Rhododendrons and other shrubs came from the nursery of Mr. G. Reuthe. Messrs. R. Veitch showed a number of interesting shrubs. They exhibited the new Corylopsis Veitchiorum, the free-flowering white heath, Erica Veitchii, Rhododendron neriiflorum, and a fine form of R. hippophaeoides, the Japanese Azaleas Kirin and Tsuta Momiji and Magnolia Veitchii, a beautiful novelty with blush pink flowers similar to those of M. Campbelli, one of its parents.

A good strain of polyanthus was shown by Messrs. Blackmore and Langdon, a fine blue primrose by Mr. G. A. Miller, cinerarias and Primula obconica grandiflora by Messrs. R. and G. Cuthbert; and sweetly scented roses by Mr. G. Prince and Mr. E. Hicks. Carnation groups were staged by three leading growers, Messrs. Allwood Bros., C. Engelmann and Stuart Low and Co. The Violets Princess of Wales, Princess Mary and Mrs. Lloyd George, were shown both by Mr. J. J. Kettle and Mr. Baldwin Pinney. The old-fashioned Dusty Miller, Primula auricula in many varieties, was exhibited by Mr. James Douglas, and a group of Caledonian strain cyclamen was set up by Mr. J. W. Forsyth. Freesias were shown by Mr. G. H. Dalrymple and Messrs. Dobbie and Co., and a group of multiflora hyacinths in bowls by Messrs. Sutton and Sons.

The most interesting alpines were in two amateur exhibits. Lady Abercrombie and the Hon. H. D. McLaren showed us some rare primulas—PP. Bulleyana, Giraldiana, Cawdriana, sino-plantaginea—and several dwarf rhododendrons, of which R. rupicola, very woody and compact with large heads of violet flowers, and R. racemosum, with pale pink flowers and red stems, were the most obviously beautiful. Large healthy plants of Androsace imbricata and A. pyrenaica studded with their minute pearly flowers showed that these high alpine androsaces are not impossible in this country.

Mr. Mark Fenwick's collection was especially interesting for its daphnes: D. arbuscula, which is said to be a local form of D. Cneorum but does not look it, for it makes a stocky little bush with large, starry flowers; D. retusa, very woody and slow growing with wide flowers of purplish pink that suggest D. indica; D. tangutica with white flowers; the now well known and very splendid D. rupestris grandiflora and D. Blagayana.

Messrs. Gavin Jones made a naturalistic rock garden with a grey mountain topped with a gnarled old specimen of Picea obtusa nana gracilis, and sparsely planted with Gentiana verna and honey-scented Thlaspi rotundifolia.

Messrs. Maxwell and Beale showed some good heathers, including the very fine deep-coloured and prostrate variety of Erica carnea called Vivelli, and several happy-looking plants of Andromeda tetragona with pinkish lily of the valley flowers and the general look of a club moss.

Stylophorum diphyllum, an excellent vigorous plant for a shady corner with crinkled yellow poppy flowers, was shown by Messrs. Cutbush with the wonderful orange-scarlet tulip T. præstans Tubergen's variety.

Messrs. Clarence Elliott showed some of the excellent forms of Primula pubescens, Mrs. J. H. Wilson (violet) and Faldonside (maroon crimson).

Messrs. Tucker showed the dead white albino of Anemone appenina and pans of small daffodils growing through a carpet of Raoulia australis and Primula Juliæ.

Messrs. F. G. Wood had a neat little paved garden round a bed containing some neat small hybrids of Primula Juliæ (some of them pale yellow), and in the background the true oxlip, an interesting hose-in-hose cowslip, Erin's Gem, and the little pink double daisy Dresden China.

Messrs. Prichard showed Viola pedata bicolor, the rare pansy from North America, which carries its velvety purple upper petals thrown back like the ears of a rabbit, a good bluish form of Primula marginata and many other things.

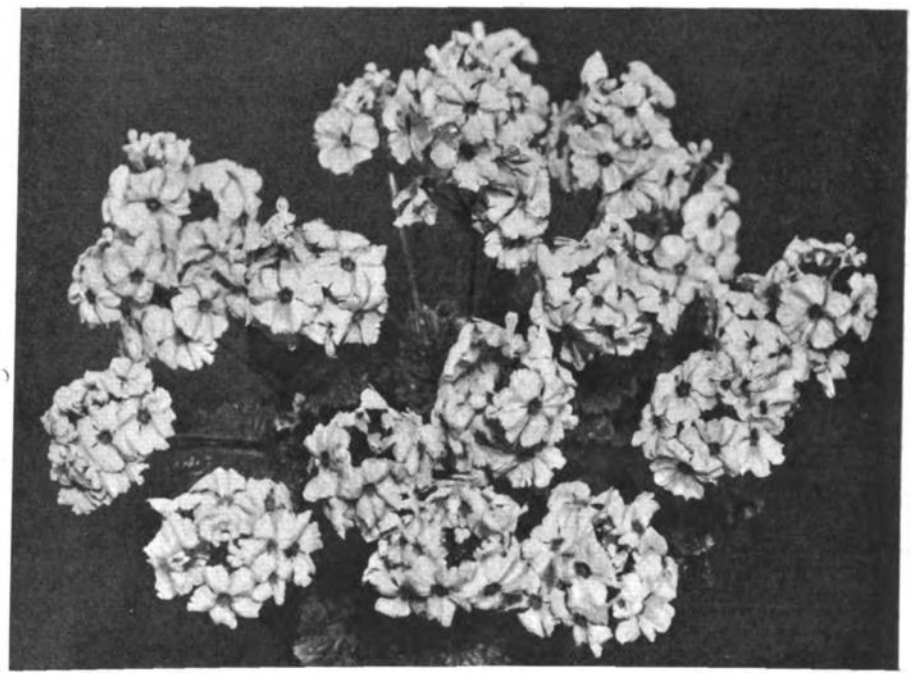
Mr. H. T. Pitt, Rosslyn, Stamford Hill, was awarded a silver Banksian medal for an interesting group containing many selected varieties of Epidendrum Endresio-Wallisii, also two well grown examples of Cymbidium Devonianum and a strong plant of Epidendrum sceptrum. A pretty species was staged in Polystacha lutescens, with erect spikes of numerous yellow flowers. Other species were Odontoglossum Uro-Skinneri album, O. pulchellum, the charming O. Rossii, and the singular Cirrhopetalum gracillimum. A similar medal was given to Messrs. Cowan and Co., Southgate, who staged a fine lot of Cymbidium hybrids, also Cattleya Tityus and C. Clotho, both well coloured, and C. Freda Sander, with pure white flowers. Miltonia Bleuana bore flowers somewhat larger than usual, and among the other popular hybrids was a pleasing variety of Odontoglossum promerens.

A silver Banksian medal was also awarded to Messrs. Sanders, who had an extensive exhibit of Cymbidium hybrids, the majority with many-flowered spikes. Cattleyas included Evelyn Sander and Mary Sander, both with pure white flowers, and the now scarce C. amethystoglossa. A pleasing species was staged in Cirrhopetalum pulchrum, and another in a richly coloured variety of Lycaste Skinneri. A similar award was given to Messrs. Stuart Low and Co., Jarvisbrook, Sussex, who staged an interesting selection of species and hybrids. The former included several examples of the pretty Oncidium cucullatum, Lycaste Skinneri and several of the popular Dendrobiums, such as nobile virginale and suavissimum. Hybrids were best seen in Cattleya Albion (pure white), Miltonia Bleuana and Sophro-Lælia Psyche with reddish-coloured flowers.

Mr. Harry Dixon, Wandsworth Common, received a bronze Banksian medal for a pleasing exhibit in which Cattleya Empress Frederick and several Cypripedium hybrids stood out prominently. Dendrobium Radiant and Odontoglossum Doris may also be mentioned.

Lady Aberconway and the Hon. H. D. McLaren exhibited Cymbidium Emery var. Tangerine, a pleasing hybrid with a spike of eight flowers. Sir G. H. Kenrick, Whetstone, Edgbaston, exhibited the scarce Dendrobium undulatum from northern Australia, and several other members of the genus. Mr. William Cursham, Thrumpton, *via* Derby, sent Odontoglossum Phyllis Cursham, a pleasant hybrid with flowers of bright bluish purple.

Messrs. Charlesworth and Co., Haywards Heath, staged Miltonia Princess Mary with the segments flushed with crimson, also Odontioda Beryl with flowers of deep rose-violet colour, and examples of their Premier type of Odontoglossum crispum. Messrs. Black and Flory, Slough, exhibited Cattleya G. P. Walker with pretty flowers of rose pink colour and a rich purple lip, also Brasso-Cattleya Albion (pure white) and S.-L.-C. Heatherwood of reddish purple tints.



PRIMULA MALACOIDES DWARF ECLIPSE.
A decided break from the type.

Messrs. Sutton Brothers, Hassocks, showed Odontoglossum crispum citrinum with yellow spotting and a richly coloured odontioda bearing the name Grisell Lady Polwarth.

NEW AND RARE PLANTS.

AWARDS OF MERIT.

CALLISTEMON CITRINUS VAR. SPLENDENS.—This species is probably the most handsome of the bottle-brushes. It is a most ornamental plant with its bright red showy flower clusters about 2–4ins. long and its long, lanceolate leaves which set off the flower-spike to advantage. An admirable decorative subject for a temperate greenhouse, where it attains a height of from 8–12ft. Shown by the Director, Royal Botanic Gardens, Kew.

RHODODENDRON LACTEUM.—This was the true plant which was shown and not the one commonly known as such. It is an exceedingly beautiful species, carrying large, compact trusses of pale yellow, wide-open campanulate flowers, some absolutely pure in colour, others showing a plum-coloured blotch at the base. The leaves of this species are also handsome, oblong-ovate in shape and felted beneath. It reflects great credit on Mr. A. M. Williams of Werrington Park, Cornwall, who showed this species, as it has the reputation of being an exceedingly difficult plant to grow well.

ACACIA RICEANA.—The acacia which was given an award under this name differs from that species in not a few respects. The award is only given subject to a change in the nomenclature. The plant shown was exceedingly ornamental with its graceful, drooping branchlets having its phyllodes in loose clusters. These are short and linear. The flowers are carried in small rounded clusters of a pale lemon yellow colour. Shown by Mrs. Charles Williams, Greenway, South Devon.

PRUNUS SALICINA SYN. P. TRIFLORA.—Sprays of this ornamental cherry showed the pure white flowers some ¾in. across borne in clusters of two or three on the naked dark smooth twigs. It is known as the Japanese plum, but is presumably a native of China. It is not such an ornamental species as some of its close relatives. Shown by Messrs. Notcutt

ANEMONE CREAGH CASTLE STRAIN.—This is an excellent strain of the St. Brigid anemones with much larger and more spreading flowers of a brighter and deeper colouring if that be possible. The colours are many and varied, from blues to reds, some showing red bars on a white ground. Shown by Mrs. Bucknall, Creagh Castle, County Cork.

PRIMULA CAWDORIANA K.W. 5741.—A recent acquisition to the muscarioides section of the primula genus. It is a neat little plant with a compact rosette of light green leaves from which arises a thin, graceful flowering stem varying in height from 9–12ins. and bearing at its apex a dense head of drooping pale lilac-blue flowers coated with farina in the throat. The flowering stem is also heavily covered with meal. Shown by the Hon. H. D. McLaren, Bodnant, North Wales.

PRIMULA MALACOIDES DWARF ECLIPSE.—This plant represents an entire breakaway from the typical P. malacoides as we know it. The habit is more or less that of P. malacoides, but is more compact. Three whorls of flowers are carried. The foliage is good and the plant is vigorous and very floriferous. The flowers are about ½–¾in. across, and are of a rosy lilac in colour with a bronze yellow eye reminiscent of an obconica type. It is likely to prove an extremely popular variety in the near future. Shown by Messrs. Sutton and Sons of Reading.

IMANTOPHYLLUM WESTONBIRT BRILLIANT.—A really wonderful variety carrying a perfect truss of flowers of a gorgeous fiery orange red in colour which gives way gradually to a pure yellow in the throat. The petals are of good substance and lend a distinct velvety appearance to the flowers, which are perfect in shape and form. The flowering stem is from 18ins. to 2ft. in height. Shown by Sir George Holford, Westonbirt.

Numerous narcissi were put up for award, and the following varieties received awards of merit:

NARCISSUS ST. BERNARD.—Shown by Mr. Herbert Chapman, Rye.

N. MITYLINE.—Shown by Mr. J. Lionel Richardson.

N. DUKE OF NORMANDY.—Shown by Mr. C. B. Blaneysied, Guernsey.

N. LOYALIST.—Shown by Mr. J. Lionel Richardson.

N. ALROI.—Shown by Mr. J. Lionel Richardson.

N. FAIRY CIRCLE.—Shown by Mr. J. Lionel Richardson.

N. GRENADE.—Shown by Mr. W. B. Cranfield, Enfield Chase.

N. ADVANCE GUARD.—Shown by Messrs. R. H. Bath, Wisbech.

N. PROSPECTOR.—Shown by Messrs. The Donard Nursery Company.

N. EVEREST.—Shown by Messrs. The Donard Nursery Company.

N. ORANGE BRILLIANT.—Shown by Messrs. R. H. Bath, Wisbech.

The following varieties secured first-class certificates:

N. GLORIOUS.—An excellent poetaz variety in which the brilliant orange frilled and crinkled cuplike corona is set off admirably by the pure white almost silvery perianth. Shown by Mr. J. Lionel Richardson.

N. BEERSHEBA.—Probably the finest pure white trumpet variety in existence. A really wonderful flower of perfect form with a long, straight trumpet rising from a shapely perianth of pure white. Shown by Mr. J. Lionel Richardson.

ORCHIDS.

CYMBIDIUM PETREL WESTONBIRT VAR. (Pauwelsii × Garnet).—A most striking hybrid. The spike bore eight flowers of deep rose-pink colour, the labellum having the apical area of solid crimson, with longitudinal lines of similar colour on the side lobes, The median lobe has a narrow whitish border line. In no other member of the genus has so much colour been seen on the labellum, and as C. Lowianum is represented in both parents, it is probable that this species has given rise to so fine a result. Shown by Lieutenant-Colonel Sir George Holford, K.C.V.O., Westonbirt, Tetbury Gloucestershire. First-class certificate.

CATTLEYA MINNEHAHA THE DELL PARK VAR. (Trianæ × Lady Rowena).—The finest variety so far produced of this beautiful albino hybrid. The petals are exceptionally well developed and pure white, as are the other segments, the throat alone showing some yellow colour. Shown by Baron Bruno Schröder, Englefield Green, Surrey. First-class certificate.

CATTLEYA TITRIANÆ MANOR HOUSE VAR.—This elegant hybrid between C. Trianæ var. Mooreana and C. Tityus bore a large flower in which all the segments are much broader than usually seen. In colour rosy mauve, the roundly formed labellum bright purple and with the margin prettily frilled. Shown by Mr. Geo. W. Bird, The Manor House, West Wickham, Kent. Award of merit.

LÆLIO-CATTLEYA RAJAH.—A showy hybrid between L.-C. Smilax and L.-C. Cupid. The erect spike bore five large flowers of bright orange yellow, the sepals and petals having crimson veining and suffusion, the labellum crimson and with the margin frilled. Shown by Lieutenant-Colonel Stephenson R. Clarke, C.B., Borde Hill, Cuckfield, Sussex. Award of merit.

POTINARA JULIETTÆ BROCKHURST VAR.—In this hybrid between S.-L.-C. Marathon and B.-C. Ena the well known colour of the former parent is much in evidence, resulting in a flower of soft carmine-rose tints, the labellum solid ruby colour and with gold venation in the tube portion. Shown by Mr. F. J. Hanbury, Brockhurst, East Grinstead. Award of merit.

CORRESPONDENCE

ROSE-GROWING UNDER GLASS.

SIR,—I am much obliged to "Hants" for the list of roses which he gave on page 150 of THE GARDEN of March 6th, of varieties which he considered suitable for a rose house. Among his selection I note that he included a few hybrid perpetuals. Now, perpetuals, apart from their beauty, size, texture and delightful fragrance, either economically or commercially, are none of them worth a trellis or permanent place in the rose house. With perhaps the exception of one or two varieties, such as Victor Hugo and Mrs. J. Laing, which may give a few straggling blooms after the main crop is over, they may all be classed as "annual croppers," one crop of flowers annually, and no artificial methods will induce them to do more.

Frau Karl Druschki is a splendid rose, but it, in particular, is absolutely hopeless for a continuation of bloom. In my opinion, if hybrid perpetuals are to be grown under glass, they ought to be grown in pots, as a matter of convenience and economy of space, as the pots can be taken inside as required and then put outside again, and the pots may be plunged in ashes after they have given their crop of bloom. In an open, sunny situation the wood will become firm and ripe. A rose house, needless to say, is not necessary in which to grow hybrid perpetuals to secure a full crop of bloom. The hybrid tea under glass is entirely a different subject, and its freedom of flowering and the successive crops of bloom it will give in a rose house—if advantage be taken of artificial heat—will prove it to be a truly perpetual-flowering plant, and may be flowered for months. As regards its bearing successive crops of bloom, as the name would indicate, the hybrid perpetual has next to no claim.—WM. GRANT, *Crathes, Kincardineshire, N.B.*

WILD FLOWER PROTECTION.

SIR,—Mr. Halliwell Sutcliffe's eloquent denunciation of the wild flower robbers must find an echo in the minds of all who love our countryside, as this wholesale despoiling seems so prevalent. Just now the school children come in from the meadows with huge bunches of wild daffodils, cyclists pass with sheaves of the flowers tied on the handle-bars and the hawker goes by with his clothes basket piled full. Perhaps in this particular case it does not really matter, for the daffodil is so plentiful that myriads still remain to gild the meadowland of many acres of Gloucestershire, but quantities are picked for no purpose whatever, and the children tire of them before they reach home and throw them away. The same thing happens to the blue bells. Though the flowers are pulled unmercifully, enough remain to give those drifts of deep blue, gleaming through the woods as if the sea

Digitized by Google

itself had invaded them. But all wild flowers cannot stand this wholesale slaughter. One of the prettiest of all grows in considerable numbers on the limestone ridges over the top of Leckington Quarry, the bee orchis. This is annually raided till scarce a bloom can be found. Last year it was even seen on a hawker's barrow, and one enterprising gentleman had for sale a target of closely packed wild flowers, a yellow ring of buttercups, white of moon daisies, red of poppy, purple of knapweed and a dark ring of bee orchis. I have an idea this orchid dies after bearing seed, for I have carefully marked plants growing, and after the seed has ripened have not been able to find any trace of the bulbous root. The lovely blue spikes of the viper's bugloss used often to be seen on the hillsides; to-day it is quite a rarity. Last summer I wanted particularly a good specimen of the pretty fringed buckbean, and asked an old friend who roams both hill and dale for pleasure and who knows every wild flower that grows, to get me one. He knew of a colony of it beside a small stream some seven miles away with many flowers out, and when his weary tramp in the broiling sun brought him to the spot he found that a nature study class from some college or school had paid a visit the previous day and the patch of buckbean was trampled into a muddy mass and every flower gone.

The suggestion Mr. Sutcliffe makes of protection by law for the wild flowers has been adopted as a by-law by the Thames Conservators, and the picking of flowers on the river is prohibited.

It seems a sad pity that the spirit of a poem by Robert Storey, the Northumberland poet, is not more in evidence to-day:

"I cam to the hill where a Boy I had wander'd,
And high beat my heart when I traced it again;
As up its steep side, now an auld man, I dander'd,
I stopt, whare a bonnie Pink blossom'd its lane:
It seem'd a wee star lighted up amang heather!
My first thought said, 'Pu' it, and bring it away'—
But a tenderer pleaded—'How soon it wad wither!
Oh! leave it to bloom on its ain native brae.'

"'For wha kens,' pled the thought, 'but this bonnie flower blooming
May hae some kind of feeling, or sense o' its ain?
It'll change wi' the lift, be it smiling or glooming,
Exult in the sunshine, and droop in the rain!
And wha kens that it has na some pleasure in gieing
Its flower to the e'e, and its sweets to the day?
That it hasna a secret and sweet sense of being?'
Sae I left it to bloom on its ain native brae."

—J. POUNSETT.

RHODODENDRON NOBLEANUM ALBUM.

SIR,—In your issue of March 6th (page 152) you said that Gill's Nobleanum album did not much resemble Nobleanum, but looked as if it had caucasicum blood in it. Nobleanum album is, of course, a caucasicum hybrid with white arboreum as the parent instead of red arboreum, as in the true Nobleanum. The cross has been made several times; the variety shown by Gill was one of the older forms and probably the true form. The form usually supplied by nursery gardeners is one with spots, and should, I believe, be called Heatherside Beauty.—L. R.

THE PRONUNCIATION OF "GLADIOLUS."

SIR,—You are undoubtedly right. This is a word of four short syllables. That the Latin tongue in classical times could pronounce them as such with an ease impossible to English is evident from the frequent occurrence of *five* consecutive short syllables in the rapid Galliambic metre, *e.g.*, in the Attis of Catullus. Virgil fitted the words abiete, ariete, pariete into his hexameter lines by giving the *i* the consonantal force of *j*, *i.e.*, of our *y*. In the same way we shall pronounce gladiolus as a trisyllable, gládyolŭs, stressing the first syllable by the necessity of English speech.—G. H. ENGLEHEART.

PRIMULA SUCCESSES AND FAILURES.

SIR,—Primula Palinuri, mentioned by "D. D. V." on page 176, is really a rock plant, like all those with the auricula type of leaf. I have a fine plant growing on the side of an exposed limestone wall 4ft. from the level and full exposed to the south-west winds, yet it is looking quite happy and coming into flower. It is also doing well on the top of the rockery, fully exposed. Primula pubescens alba is now flowering here. Farrer mentions it in one of his books as he saw it in a cottage garden near him, and again in a garden in Devonshire. My first plants came from Aberdeen many years ago, but were lost. It differs from nivalis of gardens and helvetica alba by having longer and narrower leaves, smaller trusses of flower and these hung to one side, cowslip fashion. It is also taller. P. Rhenania, a hybrid between P. marginata and an auricula, is also flowering here for the first time. It has the marginata foliage, but a tall scape of dark lilac flowers somewhat resembling Linda Pope.—JOHN STORMONTH, *Carlisle*.

BOWLING GREEN FROM SEED.

SIR,—In the issue dated February 13th a very interesting article entered into the details connected with the successful construction of a bowling green from seed. Having had some experience in "not very successful" construction, I would emphasise one part of that article on which I think sufficient stress has not been laid—that urging the sterilisation of the soil used for surfacing. Within the precincts of Greater Glasgow and under the ægis of a prominent horticulturist, lately deceased, a bowling green was constructed from seed in the grounds of a public institution. The surfacing soil was a fine black friable loam, such as delights the eye of every gardener—but it was not sterilised. We can sum up the result in a few words: for two years that green was an absolute heart-break, and even now, in its sixth year, there are obvious traces of wild growths in it. It is thus I emphasise the sterilisation of the soil used to surface all greens, preferably by heating it in some way. Only by being careful in that way can the greenmaker hope to obtain a green which, from the first, will be successful.—CLYDESDALE.

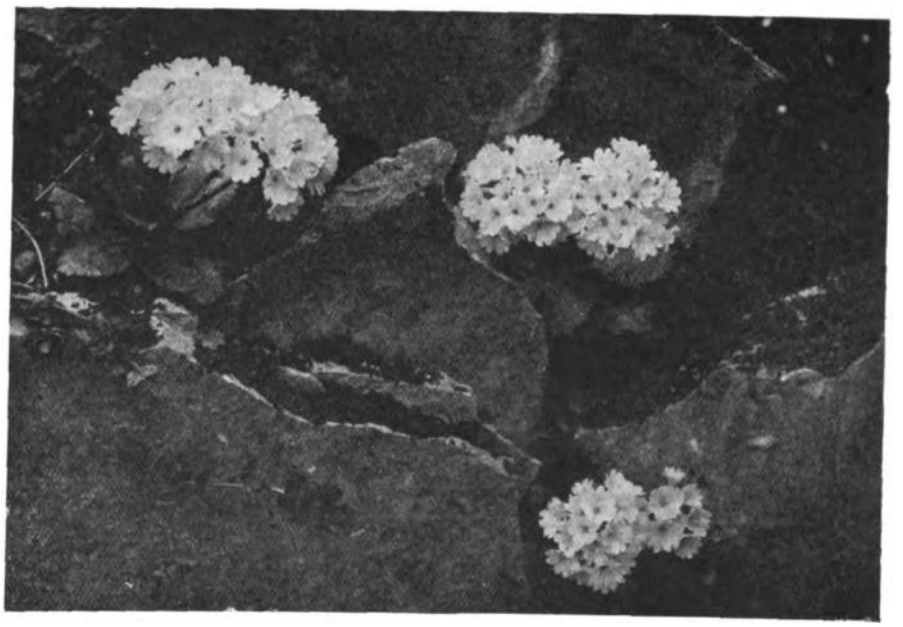
GROWING GRAPE VINES FROM EYES.

SIR,—I am afraid the amateur who tries to grow young vines on the lines laid down in THE GARDEN for March 6th would only have moderate success. Half an inch of wood each side of the eye is too little; 1½ins. below and 1in. above is much better. The top part is less important, as (in spite of the picture) the cutting *never* roots above the eye. It is best to put each cutting into a small pot separately. If lifted from a pan as shown, the bulk will probably go back and die, as no plant I know resents disturbance at the root more than a young vine, and if it once flags, either amateur or professional will find it difficult to get it up again.

As regards pinching off the embryo bunch, I have grown tens of thousands of young vines, and only once saw the embryo bunch come out on the young shoot. It was always a puzzle why, as, of course, nearly all well ripened buds have an embryo bunch in them.

As regards shaving the under side of the cutting, I once tried 200 this way for experiment, and only forty grew, as against over 90 per cent. of the regular stock.

March is rather a late start. I always used to put my cuttings in before Christmas and started them with the New Year, but an amateur with limited conveniences would, perhaps, do better to start a month or so later.—CHAS. E. PEARSON, *Lowdham*.



PRIMULA PUBESCENS ALBA, OF NEAT HABIT AND WITH DAINTY FLOWER TRUSSES.

BRASSICAS for SPRING SOWING

BEFORE saying anything about individual varieties, just a word must be said regarding the preparation of the seed bed and the sowing of the seed. The soil should be fairly rich and well worked. Fork it over as soon as possible (presuming, of course, that it has been dug some time previously), and leave for the air and sun to dry the surface before raking down to a fine tilth. Before raking down, give the soil a good dusting with lime, enough to whiten the ground. This, besides being good for the soil, will also check club root disease should it be present.

Now for the sowing of the seed. I often see seed beds where the sowing is done broadcast and I also see gardens where sowing in drills is practised. Personally, I always sow thinly in drills—for the simple reason that it is easier to hoe between the youngsters and one can easily choose the best plants. Again, there is not that overcrowding and consequent leggy plants that one gets by sowing broadcast.

The time to sow, of course varies slightly according to the soil one is dealing with and the part of the country in which one is working. As a rule one general sowing of cabbage, broccoli, Brussels sprouts, etc., is made in early April; but, where possible, it is advantageous to vary the dates of sowing, as I will endeavour to point out.

Taking the common cabbage first—I say "common" with a reason, for, although it is possible to maintain a supply of this vegetable throughout the year, excepting the coldest winter months, there is often no demand for it during the summer months when peas, beans and cauliflowers are plentiful—it is usual to arrange for a crop to mature in spring (by autumn sowing) and another for autumn, to provide greenstuff when cauliflowers, peas and beans are over, or nearly over. This crop for autumn use is the one with which we are at present concerned. April, as a rule, is early enough; but where one wishes for cabbages in, say, August, it is necessary to sow in March. Planting out should be done in June or July, as soon as the plants are ready. Where possible, the seedlings should be pricked out into nursery beds before finally planting out, but this, as a rule, cannot be undertaken owing to lack of room and the fact that so much other work calls for attention in the late spring. From among the hosts of varieties cultivated I have chosen these, not as being exceptional in any way, but as really good ones for general culture.

FIRST AND BEST.—For use in September.

ST. JOHN'S DAY.—Coming in just after the above.

WINNINGSTADT.—A useful late autumn cabbage which is a tall, conical variety and perhaps the best of all for spring sowing.

CHRISTMAS DRUMHEAD.—Not a great favourite, but useful where a smooth-leaved cabbage is required during winter.

To follow these spring sown cabbages, savoys are in demand. They stand the severe weather and, in fact, are always better for use after frost. Sowing should take place in April and the plants be put out in June or July, as soon as they are large enough and ground is vacant. The distance allowed when planting out will depend on the variety. For instance, while 15ins. to 18ins. will be ample for such a small grower as Early Man, 2ft. to 2½ft. will not be too much space to allow for Drumhead.

The best varieties for general use are:

EARLY MAN.—A small, early variety.

DWARF GREEN CURLED.—Another early variety which has much curled leaves—it looks quite pretty.

ORMSKIRK.—A standard maincrop variety, a large, firm grower.

DRUMHEAD.—Another huge late variety.

Turning attention now to the cauliflower, one of the aristocrats of the cabbage family, I really do not know when to advise sowing. Being confined to outdoor sowing I should be inclined, especially if I possessed a suitable warm border, to make a sowing in early March (weather permitting) of such an early variety as Septon Forcing or Early Favourite for use in July and August. A sowing in April of the same variety together with Purity and Autumn Giant will enable one to enjoy cauliflowers until frost comes and stains the rest. However, those who are wise will not be altogether deprived of this luxury by the first frost, for, by lifting and packing in a frost-proof shed with some soil about their roots, the season may be extended for a week or two and then—well we still have the broccoli, those hardy cauliflowers (if I may so call them) to fall back on.

The time to sow broccoli for the best results is debatable, but, personally, I like to sow my Veitch's Self Protecting (the earliest variety—to follow the cauliflowers), in March, so that I have good plants for putting out in May. The rest of my varieties are sown in April and the selection I favour to give a supply until spring are:

SNOW'S WINTER WHITE, for use about Christmastime.

LEAMINGTON.—To follow in the New Year.

LATE QUEEN.—To fill in the gap until MODEL (one of the latest), is ready for use.

When planting out choose a firm piece of ground and plant firmly.

Brussels sprouts next claim attention. They need a long season of growth and I like to sow a row or two in autumn for planting out early. When one is relying on spring sown plants it is well to raise some in heat in February and March for early use, sowing the main crop outdoors during March. As with broccoli, plant firmly and allow plenty of room There is quite a number of varieties, but the following will give satisfaction in most cases:

THE WROXTON.—Not exactly a dwarf, but still shorter than most. A good variety for early use.

DALKEITH and AIGBURTH.—Two of the best of the taller varieties.

Remember to pick the sprouts first and leave the tops of the plants till last. If you cut the tops first the sprouts will begin to open.

The last item on the programme is kale—a much neglected vegetable. It is not of such high quality, perhaps, as some of the other brassicas I have mentioned, but it has one very strong point and that is its extreme hardiness.

SCOTCH CURLED is the best variety to grow. Just one more word about kale before I finish. I wonder how many people grow variegated kale. It is worth growing if one wishes to add colour to the garden during winter. The yellows, reds and purples make rather a show if put in in time for them to get established before winter.

N. D. H.

GARDEN TECHNIQUE

FLOWER GARDEN

PRICKING OUT ANTIRRHINUM SEEDLINGS.

ANTIRRHINUMS have now come to be regarded as everybody's flower. They thrive and grow in almost any soil, and are equally suitable for the adornment of a cottage plot or for the beds in a garden of larger pretensions. Those who have sown early in February should now have seedlings sufficiently well advanced to have them pricked out. Where large numbers of plants are required, cold frames should be made ready by spreading a sandy compost of medium fine soil all over the frame to the depth of 3ins. or 4ins.; this soil should be well firmed with the feet, then the seedlings pricked off 2ins. or 3ins. distant from each other, according to their size. When each light or frame has been filled, give the seedlings a good watering, using a medium fine rose on the watering can for the purpose; then close the frame lights. Daily shading with mats while the sun is shining on the frames will be necessary for the first week or two. As soon as the little plants have got a start in the fresh soil, admit a little air throughout the day; then, later on, when no frost threatens, the lights should be left tilted at nights, and taken off throughout the day when the weather is fine.

BEDDING GERANIUMS.

ALTHOUGH great changes have taken place in the bedding out of flower beds, and even more so in the kind of plants used, yet geraniums are still used in large numbers every year to fill the borders and beds of city dwellings. There is no doubt that well grown geraniums, when planted in masses in an open and sunny position, give a decided tone of brightness to the surroundings.

Geranium cuttings are usually inserted in quantity in boxes of sandy soil in the late summer and early autumn, and wintered in a structure with an intermediate temperature. At this time these geraniums should be fairly well rooted, and to prevent giving the plants a set-back at the bedding-out time, it is necessary now to place the young plants singly into 3in. or 4in. pots, or have them mossed.

The
ATCO
MOTOR MOWER
The Sports Field—— The Small Lawn

For each there is an ATCO Motor Mower—for every size of lawn there is an ATCO machine that will prove more economical, more efficient than any other method of mowing, and will reduce the labour of maintaining the condition of turf to a negligible minimum. For the Sports Field there is the 30-inch model with, if required, a trailer seat attachment. For the suburban garden the 14, 16 or 18 inch Mowers at

Prices from 30 Guineas.

Ask any of its 11,000 users their opinion of the ATCO Motor Mower.

Write to-day for 1926 Illustrated Art Catalogue of ATCO Turf Culture Specialities giving full information—It will be sent post free on request.

What users are saying about The J·P SUPER

From a Lawn Owner: "It is the easiest machine to work devised and renders a petrol-driven motor a superfluity."

From a Lawn Owner: "No effort is required to push ths machine, which is a 16-inch.

From a Lawn Owner: "In addition to saving a man, our lawns are kept much nicer than ever before at much less cost."

From a Golf Club Secretary. "I would like to register my admiration of your Mower and gratitude for at last producing something so infinitely superior to the 'plumber's jobs' in mowing machines that we have had to suffer from so long."

From a Golf Club Secretary: "The Greenkeeper tells me it is easier, quicker and more thorough than any he has ever seen, and hopes he may never have to revert to the old type."

From a Gardener: "It is the most marvellous machine I have had anything to do with, and have used all the best makes in my time."

"It is so simple to adjust, easy running and best all-round cutting machine I know of. It is all you claim it to be."

Mossing is done by wrapping, then making secure with matting, a good handful or two of semi-damp moss all around the earth and roots of each plant as they are taken out of the boxes. It is often advisable when doing this mossing to add a little fresh soil to some of the roots before closing the moss and fixing the matting around each plant. As soon as the plants are mossed they should be set back into cutting boxes and soil placed between the moss "balls" to keep the plants upright and steady, and also to keep the roots in a properly moist condition.

The boxes should be placed in a brisk heat, and kept there until the plants have got thoroughly over the check of root disturbance. Afterwards they should be removed to cooler quarters, until eventually they can be set out in frames.

At the bedding-out period—last week of May or early in June—these mossed geraniums are quite easily removed from the boxes, and when set out in the beds—moss and all—they receive little or no check, and usually their roots have ramified throughout the moss "balls" at this time. By adopting this method with geraniums there is a great saving in pots.—DAVID ARMSTRONG.

MISCELLANEOUS

IVIES—CUTTING AND PLANTING.

IVY plants will grow in almost any kind of soil and in any position. But there are isolated cases where the plants are difficult to establish, it may be in a cold, clayey soil. In such instances I recommend the addition of some old mortar rubble to the ordinary soil; I have used it with great success in such soils. The plants require cutting at this time of the year—from early in April to mid-May, in the south, and the end of May in the northern counties. However well treated ivy plants are during the summer months, where they are grown on walls, there will be some faded leaves and other foreign matter collected behind the luxuriant foliage and when the latter is trimmed off, the collected rubbish will be exposed. It should be cleared away. Cut the old leaves well back, do not leave long leaf-stalks visible. Specimen plants of ivies, grown in flower pots, are very useful and ornamental when placed in draughty positions in or near to front porches, which are open-built, and in which few plants will live. Ivy should never be allowed to cling to living trees where the latter are valued. For establishing specimens in pots, those growing in pots in nurseries should be selected. Usually the plants are much pot-bound and should be re-potted at once in pots two sizes larger. The central stake must be a sound one and the plant trained from the first so that all sides will be well balanced.—G. G.

PLANTING JERUSALEM ARTICHOKES.

THESE may be so grown that they yield a big crop of tubers, while the stems and leaves form a really effective wind-break in the case of very exposed gardens. Furthermore, in many town and suburban gardens the stems and leaves, during the summer months, will form a screen shutting out objects that may be unsightly, such as rubbish and cinder heaps, fowl shed, pet rabbit boxes, as well as forming a division fence between the flower and vegetable quarters. Treat the plants well, dig the soil deeply and enrich it with rotted manure or hop manure if other kinds are not procurable. Select nice tubers possessing three or four eyes, plant them 5ins. to 7ins. deep, 1ft. apart in the rows and 30ins. from row to row. These are for block plantations; if one row only is required, make it a double one by planting the two rows about 16ins. apart. In heavy soils plant 5ins. deep, and in sandy or light, 7ins. Plant every year rather than rely upon straggling tubers left in the ground. From the end of March to the middle of April is the time to plant.—HANTS.

PLANTING PINE TREES.

VARIOUS kinds of pine are so useful for shelter purposes that a few points on the planting of the trees may be of interest. Many people plant pine trees with results that are anything but satisfactory and, in quite a large number of cases, the specimens die. One mistake is to choose trees that are really too large to transplant well. It is a great temptation to select specimens that are 5ft. or 6ft. in height in order to get a good effect at once. As a matter of fact, trees of this size hardly ever give good results. Healthy little trees of 2ft. or even less in height are far more satisfactory. All pines make a branch growth which is out of all comparison to their roots, and large examples usually transplant very badly. Even if they do not actually die, they will remain stationary for years and often present a shabby appearance. On the other hand, small trees re-establish themselves readily and soon start a vigorous growth. When preparing the opening in the ground for the pine tree it is essential that the bottom soil should be thoroughly loosened. It is really a good plan to spread the roots on a layer of pure sand, and this will often make it possible to establish pines on land which is not naturally very suitable. Provide each tree with a stout stake so that the roots may not be disturbed through wind action. For general purposes the Austrian and Scots pines are, perhaps, the best, although in the southern counties, especially near the sea, Pinus Pinaster and P. insignis are strongly to be recommended.—S. LEONARD BASTIN, *Bournemouth.*

SPRING-PLANTED ROSES

THE continued rains throughout last autumn and the early winter have compelled many who prefer planting their new roses during November or very early in December to carry out the work in the spring this year. The pros and cons of autumn *versus* spring planting of roses have been discussed very many times and over a long period in the pages of THE GARDEN and, to take a slight liberty with Gilbert and Sullivan, the adherents of the opposed methods have "upheld, with very little heat, their various opinions." But, be that as it may, most experienced growers will agree that in the present circumstances spring planting, with its better soil conditions, is the more likely to be successful on this occasion.

The chief enemy and drawback to success when roses are planted in the spring is the possibility of a serious check from dry weather, especially when it is accompanied by cutting easterly winds. Much as I dislike the mulching of roses planted during the autumn, I have found the practice beneficial and, indeed, almost essential, when planting in the spring has, for various reasons, had to be carried out. But mulching must not be confused with top-dressing. The former should be a comparatively loose, non-manurial material, while a top-dressing contains plant food.

The object of the mulching should be to assist in conserving the soil moisture, and it may consist of such materials as straw from the stables after the manure has been shaken out, bracken, or the late autumn's tree leaves. Failing any of these materials, recourse may be had to peat moss litter laid loosely, or even the woody and undecayed matter from the garden rubbish heap.

When the pruning has been completed, it is good practice to remove the mulching temporarily and hoe or rake over the surface soil, so as to allow sufficient air to enter. If this is repeated a few times during the early days of April, choosing warm, sunny days for the work, the roses will benefit greatly. In fact, it is not good cultivation to allow any mulching or top-dressing to remain

SALE OF ROSES
At 33⅓ per cent. less than catalogue prices.

HAVING so far sold our stock of Roses that the catalogue is no longer a reliable source of selection and not having enough each of different kinds to justify advertising the balance in named collections, we are offering what remains of our stock of bush, standard and climbing Roses in carriage paid quantities in varieties of our selection, at 33⅓% less than list prices.

The varieties are all first-class (not an obsolete one among them), the trees are excellent and, while all buyers will get remarkably good value for money the first comers will have the advantage of newer and more expensive varieties for as long as stocks last.

undisturbed for more than a few weeks, as there is every likelihood of the soil becoming stagnant. When it is impossible to obtain suitable mulching material the surface soil should be frequently stirred to keep 2ins. or 3ins. loose and thus check excessive evaporation of the soil moisture.

Particularly with light soils the planting should be done very firmly with roses of all types, and especial care should be taken to ensure that the new standard roses are securely staked and tied. Of late some nurserymen have wisely pruned the roses which have had to be despatched late in the season, so that, if they are planted as soon after arrival as conditions permit, they should be just as successful as those planted earlier in the spring.

Unless it is evident that the soil is sufficiently moist when planting roses at the present time there should be no hesitation in applying sufficient water to thoroughly moisten the roots and soil. In such cases as soon as the surface soil can be worked it should be hoed and then covered with the mulching.—A. C. B.

CATALOGUES RECEIVED.

Mr. William Sydenham, The Gayborder Nurseries, Melbourne, Derbyshire. We would draw our readers' attention to four of the well known Gay Border booklets which have just reached us. These are handy little lists which can be dropped into one's pocket easily and are most convenient in size. One deals with hardy border plants, including alpines, and a very extensive list it is, while the others give particulars of new chrysanthemums, delphiniums and Michaelmas daisies. All amateurs should procure these novel lists.

Messrs. Geo. Jackman and Son, Woking. A list of hardy herbaceous, alpine, bulbous and border plants, offering a wide selection.

Messrs. G. H. Richards, Limited, Borough, London, S.E.1. Price list of all the XL All specialities manufactured by this firm.

Messrs. Allwood Brothers, Hayward's Heath. A well illustrated list of carnations, offering varieties of perpetual flowering, perpetual malmaison, hardy perpetual border, border and Allwoodii carnations. Many novelties are offered for the first time this year. It is a catalogue which should be in the hands of all carnation lovers.

THE Amateur Flower Show under the auspices of the Royal Horticultural Society will be held at the Society's Hall on Tuesday, June 22nd. Copies of the schedule can now be obtained on application to the secretary.

WE would draw the attention of readers to the thirty-first floral meeting of the British Carnation Society, which is to be held in the Royal Horticultural Society's Hall, Westminster, on April 15th. There are numerous classes open to both amateurs and professionals, and there is a considerable list of prizes. The entries for the Show close on April 8th. The secretary, Mr. P. Bunyard, will be only too pleased to supply any additional information which may be required.

Daffodil Conference.—The R. H. S. Daffodil Show will be held in the Hall at Vincent Square, Westminster, on Tuesday and Wednesday, April 13th and 14th. On the second day of the Show a conference will be held in the Lecture Room. The morning session, from 11.30 a.m. to 1 p.m., will be devoted to diseases of daffodils, while in the afternoon from 2.30 p.m. there will be discussions on the aims of daffodil breeders and the garden value of these popular spring flowers. It is hoped that all daffodil lovers who are in London that day will attend the Conference and add to the common stock of knowledge by joining in the discussions.

WHEN ORDERING mention this JOURNAL PLEASE

MORE PROFIT THROUGH EXTRA YIELD AND *IMPROVED QUALITY.*

MATTHEWS' LAWN SAND

Effectively kills all the common weeds in lawns, and at the same time acts as an excellent Fertiliser. Sprinkle evenly over the weedy patches, at the rate of 3-ozs. per square yard, in dry weather. Repeat at intervals of a few weeks, till the weeds are killed. The grass will become brown and appear to be burnt, but it will recover, and the useful grasses will grow more vigorously.

4/- 14 lbs. 6/6 28 lbs. 10/9 56 lbs. 20/- cwt.

CARRIAGE PAID on orders to the value of 5/- upwards to the nearest station in the United Kingdom
ESSEX RESIDENTS 1/6 per cwt. less. Packing and Bags Free; not returnable.

Reg. No. 154011.

National Approval

THIS is probably the one and only instance where an honest advertiser—and most advertisers are honest—has lost the confidence of the public. The advertiser of hairpins can't sell . . . . hairpins. The cause, of course, is not so serious as it sounds. There is no reflection on **him**. The barber and the fashion have become too persuasive. Meanwhile, the slogan "Advertised Goods" continues to merit national **approval and support.**

THE GARDEN

ORCHARD GARDEN WOODLAND

Vol. XC.—No. 2838 Saturday, April 10th, 1926 Price THREEPENCE

TWO BEAUTIFUL NEW PLANTS

FOR APRIL PLANTING

MICHAELMAS DAISY BARR'S PINK.

THE FINEST PINK MICHAELMAS DAISY YET RAISED.

Excellent as a cut flower, remaining open and lasting well in water; equally charming in artificial light as in daylight.

"Until lately one had to exercise a certain amount of imagination with the pink Michaelmas Daisies, but now the pinks are really and truly pink, and of the newest varieties none is more prominent than Barr's Pink, which, with great beauty of rich colouring, combines a graceful habit, and one recognises that in this Messrs. Barr & Sons of Covent Garden have raised a variety that will long continue in the front rank of hardy flowers."—COUNTRY LIFE, Oct. 10th, 1925.

Strong plants .. .. .. per doz. **36/-**; each **3/6**

SCHIZOSTYLIS, "Mrs. Hegarty."

(NEW PINK CAFFRE LILY). This beautiful NOVELTY was shown before the Floral Committee of the ROYAL HORTICULTURAL SOCIETY on October 18th, 1921, and was at once given an AWARD OF MERIT. The flowers are of a beautiful satiny rose-pink, and keep on opening out in succession for a very long time. The general habit of growth is that of *S. coccinea*; it is as hardy and requires the same treatment.

A charming pot-plant .. .. per doz. **12/6**; each **1/3**

BLACKMORE & LANGDON - - - BATH

A Prolific Garden

cannot be maintained without the aid of some kind of manure. Stable manure is now scarce, and is bulky to cart and spread on the land. No artificial will altogether take the place of natural manure, but a good well-balanced fertiliser, used during the growing season, is a wonderful aid in producing high-class garden crops. No fertiliser is cleaner, more effective, or economical than

PEARSON'S CHEMICAL MANURE

which is compounded from the purest chemicals. It contains every element necessary to plant life which is not present in any ordinary garden soil. A glance at the analysis will prove that this manure is as cheap as any on the market, while nothing can beat it in ease of application and results.

ANALYSIS

PEARSON'S "CHEMICAL MANURE"
(ARTIFICIALLY COMPOUNDED)

Contains at least 11·79 *Phosphates soluble and insoluble;* 6·68 *Potash;* 6·44 *Nitrogen* (*Ammonia Nitrogen* 4·56, *Nitric* 1·88).

Per cwt. 25/-, ½ cwt. 13/- carr. paid. ¼ cwt. 7/-, 14 lb. 4/6, 7 lb. 2/9, carr. forward.

VARIETY IN VEGETABLES

THE fact that at the French market the other day I was able to get what the French call mangetout suggests to me that I might again draw attention to the fact that we do not have sufficient variety in our vegetables. Last time, I suggested that we cooked vegetables in a dull fashion, thereby bringing down on my innocent head the wrath of several readers who apparently live for cabbage boiled railway fashion and cut in slabs. This time I shall try suggesting a few out-of-the-way vegetables and salads, and, lest I be accused of advocating plants that are not obtainable here, let me point out that in every case seed can be bought in this country from our own seedsmen. Also, I should state that these suggestions are for additions to our vegetable supply, not as alternatives. No one knows better than I do the succulence of a dish of home-grown peas, or the satisfaction gained from a generous spoonful or two of "chapped neaps."

Few people probably know what mangetout is. It is the French sugar pea, with a pod flatter and wider than the ordinary pea. The novelty about it is that one eats the pod and the pea inside it. The pod is chopped in coarse slices, boiled in the usual fashion and then eaten, after being mixed with a generous lump of butter and a little sugar. The succulence of this dish is wonderful, and, in addition, it is economical. Incidentally, too few people realise how pleasant is hot beetroot cut in cubes with a cream sauce poured over it. But I am off on cooking again. Another excellent vegetable for cooking is the Couve Tronchuda, or Portugal cabbage. In this the leaves have prominent white midribs, which are used in the same way as seakale.

Two plants that are not quite hardy are the aubergine, or egg plant, and sweet corn, or maize. The former is a solanum and in this country requires a greenhouse for real success. It is eaten either fried in slices or stuffed, and is useful, as it comes in early autumn, when our own summer vegetables are inclined to be tough and the winter supply is not fully advanced. The sweet corn is quite easily managed if it is started in the greenhouse and planted out when it is about 18ins. high. This is also a good early autumn addition to our vegetable supply. The cobs should be picked when the seeds are just on the point of turning from green to yellow. It is very excellent, but messy, when eaten like you play a mouth organ. Warning: it only requires boiling for a very few minutes, otherwise the skins of the seeds become tough.

It is in salads that we as a nation particularly lack variety. For instance, few people grow corn salad, what the French call mâche, a very hardy and useful salad for the autumn and winter. The seed should be sown in early autumn, when a plentiful supply of the tender leaves will be available throughout the winter. Chicory is not so uncommon, but still it should be grown in every garden, for it is not only good cooked, but also as a salad. I have found that most people in this country do not start blanching it early enough, the consequence being that the outside leaves are inclined to be coarse and so a part of the plant is wasted. The common chicory, what the French call Barbe-de-Capucin, an attractive name, on the other hand, is uncommon. Its curious beard-like growth is, perhaps, against it, but when blanched it is excellent in a salad and not so tough as Chicorée frisée (endive) is inclined to be. We are also inclined to neglect the simple herbs and leaves that are so popular on the Continent and mean so much, not only in French cooking, but also in salads. Sweet bay leaves give an excellent flavour to a stew, while tarragon and chervil are, to my mind, a necessity in a salad. A teaspoonful of chopped tarragon and half the quantity of chervil add a piquancy that is often lacking, particularly as the usual vinegar of the malt variety is harsh and tastes of nothing in particular. Not only are these common herbs rarely grown in the ordinary garden, but they are difficult to find in shops.

We are so good in our peas and beans and sprouts that one might imagine that we had a sufficiency of good vegetables, but even the best palls if it is seen every day. It is surprising how a slight change makes one appreciate our good standard vegetables all the more. I think it is the constant change rather than the quality that makes one realise the importance of vegetables as an article of diet on the Continent, that and their excellent habit of having a separate vegetable course. I can strongly recommend ringing the changes in our own home grown supply; for one thing it would save an immense amount of money being sent abroad in payment for imported tinned vegetables.

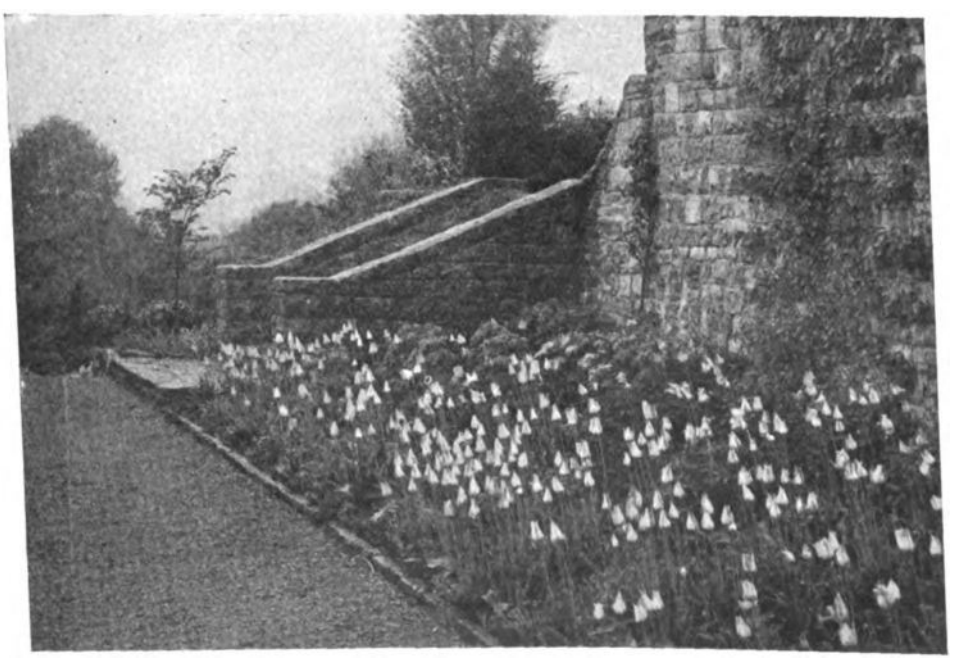
NOTES ON TULIPS IN THE GARDEN

BY THE LATE REV. JOSEPH JACOB.

WITH THE APPROACH OF THE TULIP SEASON READERS MAY LIKE TO COMPARE THEIR IDEAS OF PLANTING WITH THOSE WRITTEN BY ONE WHO WAS AN ACKNOWLEDGED EXPERT.

EXCEPT for a very few, a mere handful of enthusiasts, who grow tulips for show and who are, as it were, a law unto themselves in their methods of culture and in their aims, tulips are valued and wanted for garden decoration. When they are used in herbaceous borders it must of necessity be in the form of clumps; their number and size will depend upon what room there is among the other occupants and the taste of the planter. Three practical considerations must have weight, whatever is decided upon, if the best results are to be obtained: (1) It should be remembered that tulips should be lifted every year. From my own experience, and from all that I am told by others, I am quite convinced that this is far and away the best plan to adopt with all tulips, and that it is only in exceptional cases that a clump is as good the second time of blooming as it was the first, if it has been left in the ground all the time. In very light soils and in places where there are not many slugs, tulips may remain undisturbed for years, but the size of the flower will be very different from what it would have been if the bulbs had been taken up every year.

AN EFFECTIVE BED OF THE GORGEOUS COLOURED PRIDE OF HAARLEM.



ANY BORDER GIVEN OVER TO SUMMER FLOWERING PERENNIALS CAN BE MADE BRIGHT IN SPRING BY A FLOURISHING COLONY OF GOLDEN CROWN TULIPS.

(2) It should be borne in mind that slugs are fond both of the bulbs and the leaves, and that it would, in consequence, only be courting disaster to plant in parts where it is known these little pests are rife. Nothing looks worse than damaged leaves. Beautiful flowers with miserable foliage look like rings on dirty fingers. Should there be occasions when it is necessary for any reason to make the attempt, traps must be set until the slugs are conquered. (3) The question of backgrounds is most important. A dark hedge or foliage, such as that of Cupressus Lawsoniana, demands bright and light colours, and not such dark varieties as Fra Angelico or Faust. A hedge which will be clothed with fresh green leaves at blooming time may have anything put in front of it. Dark or light, bright or dull shades will be set off equally well. A brick wall spoils many reds, but is the very thing for all mauve and purple shades, and also for yellows. But surroundings must not be lost sight of. If the tulip clumps can rise from a mass of green, so that a large proportion of the bed is covered, their general effect will be all the better. Where collections of perennial phloxes or of Michaelmas daisies are grown in beds by themselves, they might very suitably have tulips planted between them and an early summer show obtained as well as an autumn one. And now a few words about magnified clumps, or, in other words, beds. A large mass of colour is always effective, and, although scoffers may say that to be fascinated by it indicates a bizarre taste, I must candidly own up to much more than a sneaking liking for the barbaric splendour of, say, two hundred Farncombe Sanders, Pride of Haarlem or Petrus Hondius in one big blaze. A break away for this purpose is the branching Mons. S. Mottet.

To begin with, it opens white and ends off rose, much in the same way that Picotee does, so it is never quite the same two days running. Again, its blooms are of varied heights and sizes, so it is much less stiff in a mass than an ordinary variety. A round bed of it, in my garden was greatly admired on account of its graceful appearance. I have found it to be a good laster. To get a first-rate show, only *large* bulbs must be planted, and the soil in which they are to grow must be *rich*. The following are some suggestions for beds:

(1) De Wet and Cardinal Rampollo, mixed.
(2) Prince of Austria (early)
(3) Scarlet Mammoth (mid-season)
(4) General de Wet (early, orange)
(5) Millet (crimson Darwin, late)
(6) Mons. S. Mottet (branching late)
(7) Marksman (late)
(8) Electra, Erguste, Euterpe, Gudin, Dream, Bleu Aimable, Salomon

Digitized by Google

and Duchess of Hohenberg (all lavenders or mauves), with a *very few* dark flowers, such as Viking, Moralis, Jubilee and Faust here and there among them.

(9) Suzon, L'Ingénue, Sophrosyne, Maiden's Blush, Fanny, Flamingo and Mrs. Cleveland (all some shade of pink), with a few tall, smoky tinted varieties such as Remembrance, La Tristesse and Ronald Gunn.

(10) An early variety, such as Vermilion Brilliant, planted alternately with a late cottage or Darwin—if a red, say Eclipse or William Pitt. As soon as it is over the early variety must be cut off at ground level: thus two displays are made, and each can be varied to suit individual tastes. The early variety should be a cheap one, as it has to be sacrificed, and should be as early a one as possible.

(11) A higgledy-piggledy mixture of a dwarf-growing kind with a taller one—say The Fawn and Mrs. Kerrell, Prince Albert and Golden Bronze, Isabella with Picotee, Golden Crown with Mrs. Moon, and Inglescombe Yellow with Ellen Willmott.

(12) Small bed of the dwarf yellow and white Dasystemon (species).

(13) Entire beds of broken tulips mixed together, if the bed is large enough. They are not so effective if there are only a few.

(14) Entire beds of a mixture of Darwins and cottage varieties. I like this better than a bed of Darwins alone.

The above suggestions it will be noted are samples of what may be done with tulips alone. If notes are made at the time of flowering of what strikes us in the gardens we visit, it is an easy matter to expand the above list to any extent.

EARLY SPRING in an EAST YORKSHIRE GARDEN

THIS INTERESTING ARTICLE SHOWS THE VALUE OF KEEN GARDEN OBSERVATION WHICH ALL GARDENERS SHOULD PRACTISE.

THE Christmas rose, Helleborus niger, usually the first winter flower to be noticeable and well out by Christmas, did not come into flower until well into January, along with the green-flowered British species, H. viridus. Snowdrops, S. nivalis, were noted in flower on January 27th, three weeks later than 1925. They grow and flower very freely, revelling in the open poor soil in or near the roots of box, euonymus, privet and other evergreens and also where the ground is sucked pretty dry by tree roots. This is a hint that might be acted on by readers who find difficulty in establishing this welcome, if rather "icy" cold white flowered species. The position is one that might also be worth trying for some of the southern European or Eastern bulbs, such as bulbocodiums, tulip species, etc., that may possibly flower once and then disappear, probably owing to damp conditions that you never find where box and many other evergreens keep the soil well drained and always open. The double snowdrop, S. nivalis fl. pl. comes into flower much later. A small group of Iris histrioides which has been in its present position for some years, produced its very lovely short stemmed flowers from February 2nd onwards, fourteen days later. I. stylosa commenced about the middle of the month and I. reticulata on the 28th, curiously a week earlier than the previous year, producing a magnificent lot of flowers which, unfortunately, have hit on rather a bad spell, high winds followed by frost and snow on March 3rd and 4th, which will, I am afraid, hurry them over.

THE PRETTY DEEP BLUE ANEMONE BLANDA.

CROCUS VERSICOLOR, ONE OF THE LATEST TO FLOWER.

Daphne Mezereum and D. M. alba, along with Jasminum nudiflorum, are surely among the loveliest of easy shrubs for winter flowering. Although a little later than usual, they have been magnificent this year. D. M. alba especially, with its long spikes covered with white scented flowers. It seems strange that this shrub, which, with ordinary care, thrives even in town gardens, is not more freely planted, not only in private gardens but in public parks, in which, in most instances, early flowering shrubs and flowers seem to be totally neglected. My daphnes are all on their own roots, mostly being self-sown in various parts of the garden, no doubt with the assistance of birds, which only too readily strip the seed berries off. If it is possible to cross this species with D. Cneorum, some hybrids of garden

Digitized by Google

value might result, as they do not bloom at the same period it would be necessary to bring the D. Cneorum into flower earlier inside for purposes of cross-pollination.

The great joy has been in the lovely crocus species, which have been fine, and especially so in the last few days of February, when, due to milder weather conditions, after the winter hold up, they came out with a rush. Not a single species ventured to flower in January, the first appearance being C. Sieberi, on February 5th, with its dainty and always welcome lilac blue flowers, four weeks later than in 1925. C. Imperatii, from the mountains near Naples, the finest of all the crocus family, was in bud on February 7th, but not fully opened until February 18th, six weeks later than last year. It is as lovely in bud, with its large, fine buff ground, darkly feathered outer leaves, as when fully opened out on sunny days and showing its beautiful soft lavender purple inner leaves. My clump of this species is the result of three bulbs which were planted in 1916 in the position that they at present occupy in the garden. C. candidus is a species from Asia Minor, with pretty white flowers with yellow base when fully opened and with the back of the outer segments stippled with a purplish blue. It began flowering on February 10th, or three weeks later. The bulbs were obtained in 1916 and placed in a portion of the island moraine and numberless seedlings have come up all round. The yellow-flowered var. sub-flavus, is also alongside and is usually a fortnight or three weeks later in making its appearance. On February 12th mice commenced to eat down to the ground clumps of the yellow garden crocus. Traps were set, but only resulted in odd long-tailed field-mice and a single pigmy shrew being taken, and the eating down continued in all parts of the garden until a hard frost set in.

C. Tomasinianus flowered from February 18th, fourteen days later. This is probably the most useful of the early flowering species. A native of Dalmatia, it is an easy doer in our gardens, it seeds freely, perhaps too freely if among precious plants. Its groups of flowers are an outstanding feature in the garden, especially if you have the more robust form, with ashen grey outer segments to the perianth, intermingled with those that have a grey base and lovely deep lavender darker flushed upper segments. They are then quite as lovely in bud as when fully opened out. It stands unsettled weather conditions quite well and flowers over a long period. C. susianus, with its yellow dark purple feathered outer leaves and brilliant golden yellow lovely star shaped flowers when fully opened out in the sun, came into flower on February 20th, a week earlier than in 1925, as did also C. Korolkowi, a dainty, but rather fragile small flowered species from Turkestan, having fuscous brown outer leaves and brilliant yellow star-shaped flowers. A delicate little species received as C. heufellianus, has dainty blue lilac rounded flowers, slightly tinted yellow at the base inside, with orange stigma. One variety of this has the outer leaves darkly feathered. The last two species to appear are: (1) the so-called Scotch crocus, C. versicolor, which grows wild in the Riviera (and not in Scotland); it is one of the Imperati group and the usual white flowers, with the outer petals feathered deep purple, is one of the hardiest, prettiest and easiest of the crocus species; (2) C. biflorus of gardens, according to Bowles probably a seedling form of C. versicolor; it is a hardy and free growing species, increasing very freely, too freely for some positions, opens its flowers in masses whenever the sun blinks out, and is very attractive to bees.

Mild windy weather, with more frequent sun, brought many other plants into flower towards the end of February, among them being the pretty deep blue Anemone blanda, a fine lot of A. triloba, including white, rose and some lovely deep blue flowered self-sown seedlings, and one with very large green bracts, much larger than the blue petals at first, but eventually the blue petals just about got equal with them. The dwarf daffodils, Narcissus minimus and N. nanus, which come into flower year after year, some of the latter from under the shade of good sized plants of Acantholimon glumaceum and A. venustum, such positions as I noticed some bulbous and other plants occupying in hot positions in the Sierra Nevada. One of the prettiest of the fumitories is Corydalis cava alba, with beautiful white flowers which, when fully developed, look not unlike a white-flowered orchis spike at a distance. Primula marginata, in two forms is in full flower, with its fine powdered serrated leaves and rosy pink flowers, one variety having a much more prominent yellow eye. Other primulas are trying to show, including the large Italian P. Palinuri, which I had had outside for some years.

An exceedingly pretty plant for peaty soil in a shaded position is Synthyris reniformis, which is now carrying its lovely bright pale blue flower spikes, to which the shapely dark green foliage provides a pleasant foil. In a recent issue of THE GARDEN, Muehlenbeckias were recommended. I agree that they have very pretty foliage and are useful for the positions named, although there are many plants that produce much more attractive flowers that would be preferable. My experience with Muehlenbeckia nana has been rather an unpleasant one. Placed in the stone joints of a built-up moraine it pushed its roots in behind and came up into the moraine through 2ft. of grit to the surface, running its roots about in all directions. It entailed taking down a considerable portion, including the disturbance of many much more valuable plants before it could be got out and, I hope, exterminated. It has also taken possession of another part of the garden, strangling everything else as it goes along. Hence this warning.

T. ASHTON LOFTHOUSE.

Linthorpe, Middlesbrough.

SHRUB FOR WALLS

BY W. J. BEAN.

(*Continued from page* 174.)

ALTHOUGH it has no flower beauty to recommend it, COCCULUS LAURIFOLIUS, a Himalayan shrub, is one of the handsomest of evergreens. It has lance-shaped leaves about 6ins. long, conspicuously three-ribbed and of a dark shining green. It may be recommended to those who like to grow uncommon plants.

COROKIA.—Three interesting New Zealand evergreens belonging to this genus may be grown on walls, *viz.*, buddleioides, Cotoneaster and virgata. C. Cotoneaster is, I think, the most attractive and makes a very pleasing covering for a wall up to 7ft. or 8ft. high. Its thin wiry twigs, tortuous and interlaced, bear tiny leaves, dark green above, white beneath, and, in May, quantities of small, star-shaped, bright yellow flowers, ¼in. wide. It requires very little pruning and may be allowed to grow well away from the wall. C. buddleioides and virgata have yellow flowers also, but larger leaves.

COTONEASTER HORIZONTALIS.—This is, of course, perfectly hardy, and is ordinarily a flat-growing, almost prostrate shrub, but planted near a wall, it will grow erect and spread itself out near the wall without actually pressing against it, in that way giving a charming effect, especially when freely set with its brilliant red fruits. I have seen it growing like this against a wall with a northern exposure, and it is worth noting by those who want shrubs for such a place. It is deciduous, but the leaves fall late, often changing to orange or red before they drop.

CYDONIA.—All the quinces are hardy, but several are grown against walls. C. japonica, for instance, will bear 30 degrees of frost without injury, but is, nevertheless, often given a place on a south wall, because it blossoms earlier there, its blood red flowers commencing sometimes to open in December, or, if the winter be severe, in February and March. It flowers from the lower leaf-axils of the preceding summer's growth or from spurs on still older wood. The varieties sinica and cardinalis are very rich red; nivalis is a good white; aurora a beautiful rose suffused with yellow. C. cathayensis is also used as a wall plant, because it usually bears fruit more freely there; but it has a gaunt, thin habit, and is chiefly of interest for its very large fruits, often 5ins. or 6ins. long and half as much wide.

Digitized by Google

CYTISUS SUPRANUBIUS.—This broom is found wild on the Peak of Teneriffe and, except in our warmer climates, needs a wall. In habit and branching it resembles the well known Spartium junceum, but the flowers are much smaller and creamy white, opening in May. A very charming shrub. A neighbour of this is C. palmensis (sometimes regarded as a variety of C. proliferus), the "Tagasaste." This has the trifoliate leaves of the brooms in general, and is a tall shrub of graceful form adapted for covering a pillar. Flowers white. May.

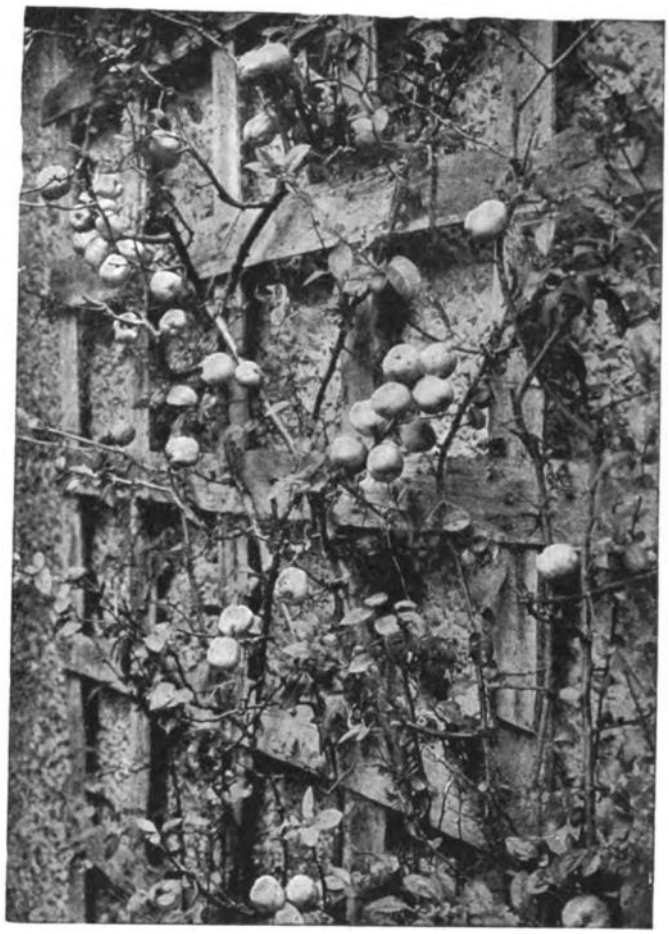
DECUMARIA BARBARA.—A deciduous climber related to the hydrangeas and clinging to the surface of a wall or other support by means of aerial roots. The small white flowers are in trusses 3ins. wide. I saw a very fine specimen covering a wall 10ft. or more high, in Sir Stuart Samuel's garden at Chelwood Vetchery, near Ashdown Forest, in bloom last July. This is by far the best specimen I have seen, and makes a neat, close wall covering. South-eastern United States.

DENDROMECON RIGIDUM.—Belonging to the poppy family and coming from California, this beautiful shrub needs the heat and protection of a sunny wall. It will reach to the top of one 10ft. or 12ft. high, and does not need hard pruning. The leaves and young shoots are glaucous and the fragrant flowers bright yellow, 2ins. to 3ins. wide, and continue to open during all the summer and autumn months.

DESFONTAINEA SPINOSA.—This evergreen shrub, with its holly-like leaves and its funnel-shaped, scarlet and yellow flowers, so well known in the south-west of England and the west coast of Scotland, is nearly hardy and should succeed planted at the base of a wall facing north-west, or one shaded in the hottest part of the day.

DRIMYS WINTERI.—At Nymans in Sussex, Colonel Messel has a fine plant of this evergreen growing against a wall. It was, when I saw it a few years ago, approaching 20ft. in height very luxuriant, and grew out several feet away from the wall. This species is, in fact, hardier than has been generally supposed. When well furnished with its fine clusters of white flowers, which come at the end of the shoots in May and are admirably set off by the luxuriant foliage, it is both elegant and beautiful. It comes from Chile. D. aromatica, a sturdier, dwarfer shrub from Tasmania, is not so attractive in flower, but has rich red young shoots. It also succeeds well as a wall shrub at Nymans, where it blossoms in April.

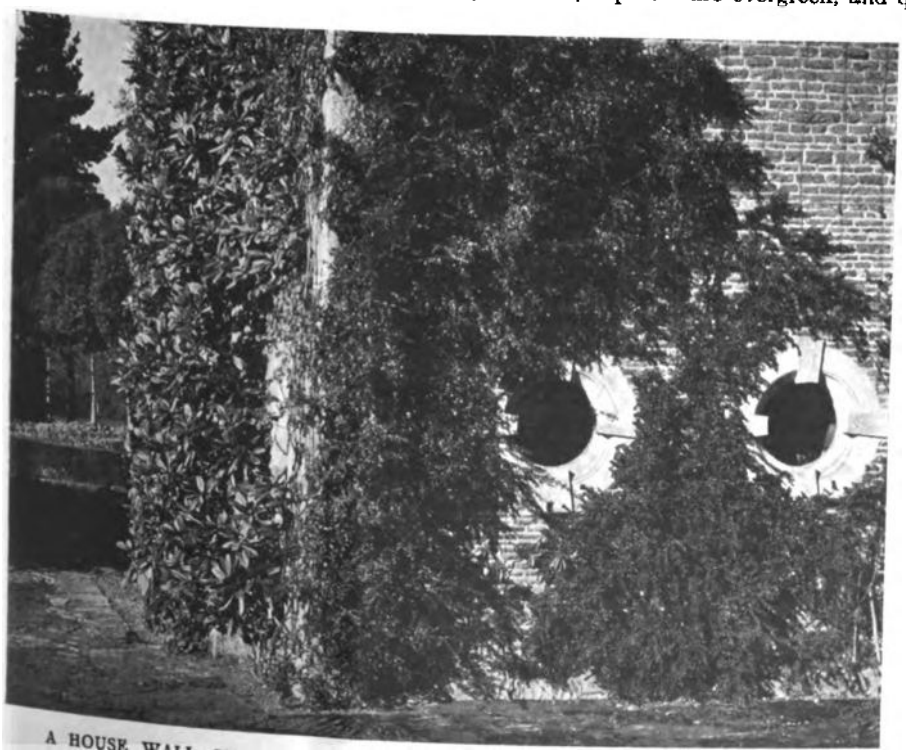
ERIOBOTRYA JAPONICA.—To those desiring an evergreen shrub with unusually fine, handsome leaves, this may be recommended. It will grow to a height of 20–30ft., and as its leaves are from 6ins. to 12ins. long and nearly half as wide, it gives a striking effect. One must not, however, expect beauty of blossom, for it does not flower freely, and it has rarely ripened fruit except in unusually favourable places.



CYDONIA JAPONICA IS NOT ONLY HANDSOME IN FLOWER BUT ALSO IN FRUIT.

ESCALLONIA.—All the escallonias that need wall protection are evergreen, and quite an interesting selection may be made from the genus. EE. rubra, exoniensis, illinita, viscosa, as well as langleyensis and its group of related hybrids, may be accounted hardy enough near London to do without wall protection. Of those needing it, E. montevidensis (often erroneously called floribunda) is a very pleasing shrub with white blossom; E. pterocladon (nearly hardy), E. pulverulenta and E. revoluta are others. Those with red flowers are organensis, a sturdy grower; E. punctata, nearly hardy; and E. macrantha, the species with brilliantly dark green foliage and rich red blossom so much planted in the south-west, often for hedges. All these are valuable as flowering from June onwards; and all, except the hybrids, are of South American origin.

FABIANA IMBRICATA.—I remember, one day during late May, some years ago, seeing a bush of this growing in Mr. H. W. Grigg's very interesting garden at Cann House, near Plymouth, perhaps 8ft. high, but more in diameter, which was one of the most beautiful objects I have ever looked upon. It was growing against a wall without being trained on it, and made an elegant, loose-growing mass, every one of its slender shoots being transformed into a long raceme of pure white blossom. Farther north we cannot, I



A HOUSE WALL SUITABLY CLOTHED WITH COTONEASTER AND MAGNOLIA.

Digitized by Google

fear, hope to reproduce such an effect, but the shrub is well worth giving wall shelter to, especially away from the region afflicted by London smoke. It likes a sunny position. The flower is a slender tube ¾in. long, the foliage heath-like. It belongs to the solanum family and comes from Chile.

FEIJOA SELLOWIANA.—Naturally, this is an evergreen shrub or small tree, but, coming from South Brazil and Uruguay, it needs wall protection except in the milder districts. It has dark lustrous green, oval leaves, 2ins. or 3ins. long, covered with whitish felt beneath. It flowers on the lower part of the current year's shoots in July, the blossoms being solitary, 1¼ins. wide, with the four rounded petals deep red, but whitish at the margin, while a conspicuous cluster of long, rich crimson stamens fills the centre. It is a flower very characteristic of the myrtle family to which it belongs. Grown on a wall, this shrub must not be too closely pruned; each year after flowering it should be thinned out by cutting away the strongest out-growing branchlets, not pruned back all over.

(To be continued.)

NOTES OF THE WEEK

PLANTAIN LILIES: IDEAL PLANTS FOR SHADY POSITIONS.

MAY I be allowed, at a season when so much planting is being done, to call the attention of those who have not hitherto grown them to funkias or plantain lilies, as being especially suitable for shady places in the garden, and extremely hardy withal? Last winter, severe as it was for a time, does not appear to have interfered with their progress, as in the middle of March clumps in my own garden were on the move. They meet, to a large extent, the solving of the problem of the shady garden, and will thrive planted under trees. Early in May they unfold their attractive foliage, and in June and July the lily-like flowers appear. They are not over particular in regard to soil, a stiff loam suiting them very well, and, given a representative collection, one may, with these hardy herbaceous plants, transform a sombre corner of a garden into an attractive place when the foliage broadens into beauty. In some instances the leaves possess the greater charm, I think. The following are all worthy of culture:

F. grandiflora.—Foliage pale green, flowers in white spikes.

F. Sieboldi.—Large grey-green leaves, lavender flowers.

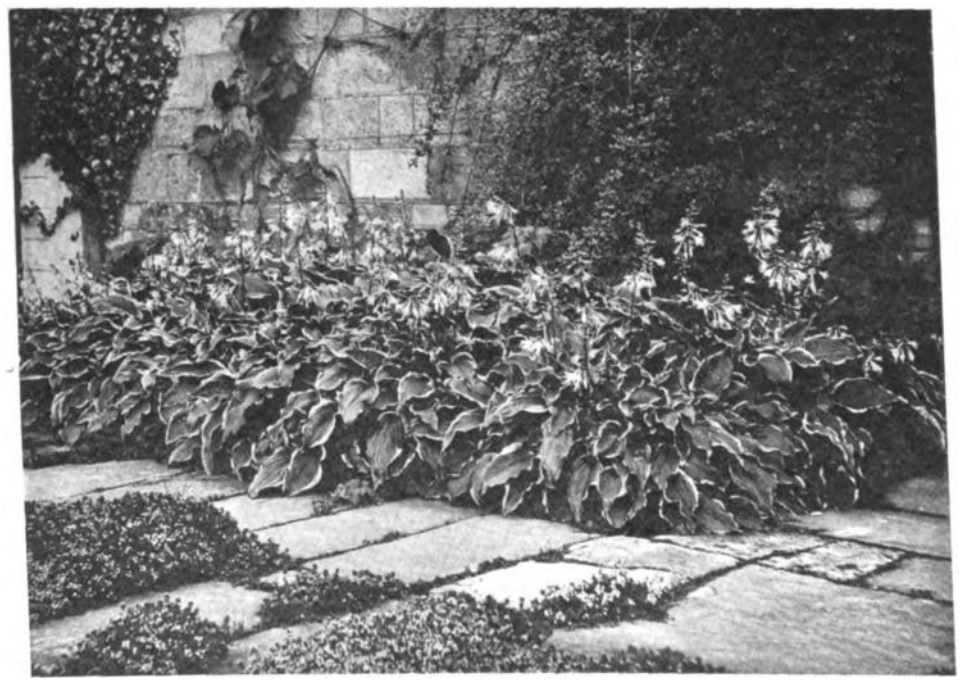
F. undulata variegata.—Pale green and yellow leaves.

F. aurea marginata.—Striped yellow leaves.

F. Fortunei.—Grey-blue leaves, heart-shaped mauve flowers.

F. ovata.—Deep green leaves, mauve flowers.

F. lancifolia.—Narrow green foliage.—W. LINDERS LEA.



FUNKIAS MAKE IDEAL SUBJECTS FOR A SHADY GARDEN.

REFLECTIONS ON THE ORIGIN OF VARIETIES.

IT has often struck me what little we know, generally speaking, of the origin of most of the popular varieties of flowers, fruits and vegetables of to-day. Hybridists rarely make the results of their crosses public property, although catalogues occasionally mention the parents of varieties when this information will not tend to react unfavourably on sales. There is, of course, no means by which one can gauge the approximate percentages of varieties which have originated firstly, as a result of artificial cross-pollination; secondly, by natural cross-pollination; thirdly, as natural "sports" or "breaks"; and lastly, by the selection and improvement of existing strains. I suppose the majority are like Topsy, they "just growed" and were spotted by the keen eye of someone who appreciated their value and possibilities. I may be of a particularly curious turn of mind, but it stimulates my interest, for instance, in the apple Allington Pippin to read that it was raised from a cross between Cox's Orange Pippin and King of the Pippins. Remembering the qualities of both parents, one is intrigued into wondering whether it combines their good points. The Worcesterberry (gooseberry × black currant) or the new Veitchberry (raspberry × blackberry) would hardly be as attractive to possible purchasers if the information concerning their origin was withheld. There seems to be many cases where a valuable variety has been well known for many years in the immediate locality where it was originally found or raised but has not appeared in general commerce for many years. Again, the public often take years to find out the real merit of a particular variety after it has been introduced through the medium of the nurseryman or seedsman's catalogues and the horticultural Press.

In talking with an elderly relative a day or two ago, this subject cropped up, and she told me of the origin of the apple Chivers' Seedling, which, I think, will bear repeating, for although this variety does not appear in many modern catalogues, it is fairly well known. Her grandfather raised the apple. One day he asked my relative to pick out the pips from a mass of rotted apple pulp. He had saved an apple or two, she thought, from every variety in the orchard; in all, nearly a teacupful of pips were obtained. Then she helped him to make crude plant pots out of clay and chopped straw which were afterwards dried off in the sun. She remembers this incident quite well on account of the child-like pleasure it gave her to make these pots. To return to the pips. These were sown rather thickly in the home-made pots, and the seedlings, when large enough, were planted in one long row in the garden. In time they bore fruit, and an apple or two from each little tree was sampled and judged, both from the dessert and culinary points of view. There must have been a couple of hundred trees or more, but only two were deemed of sufficient merit to save, all the others were destroyed. One of these, apparently, was kept just because it was a freak; it would not cook, neither was it of any use to eat raw. Its only good point was that it would keep for a twelvemonth. Her grandfather called it the "Bitter-sweet" apple. The other apple greatly pleased him. It cropped freely, was well above the average for dessert and cooking purposes and, best of all, when baked whole it needed no sugar (evidently sugar was dear in those days). Gradually the apple found its way into most of the gardens in the district and was named after its raiser Chivers' Seedling.

Judged by modern standards, Chivers' Seedling cannot be called first class. It is not quite large enough, and has no colour with the exception of a reddish flushing near the stalk, which, by the way, I fancy is unique. This apple, which was saved nearly three-quarters of a century ago because it "needed no sugar," has seen its best days, but perhaps its history may interest readers of THE GARDEN who know it.—S.

[We would welcome accounts of the origin of any popular variety of flowers, fruits or vegetables from other readers where the information is interesting and not generally known.—ED.]

ARSENIC IN APPLES.

I SUPPOSE all readers are by now familiar with the heading I have chosen for this article. It has been made very familiar to many newspaper readers by certain people. My object in writing is in answer to many queries concerning the use of various washes containing arsenic in some form or another for spraying apple and plum trees.

In the first place, for what pests do we use arsenical insecticides? Being a stomach poison, we naturally assume it is only of value against biting insects, and that is the use we put it to. Caterpillars in particular are dealt with by these means. Now, in dealing with any pest, we attempt to eradicate it in the early stages of its life-history, therefore we spray as soon as the pest is seen, usually in May and very seldom later than early June.

Of course, were gooseberries, which are to be picked soon, sprayed with one of these washes, it would be very risky to eat the fruit, but with the apple it is very different. During the normal English summer we have more than enough rain to wash off any arsenical deposits from fruit picked in autumn. Most of our biting and chewing insect pests have in England only one generation in the course of the year, so that the early sprayings with arsenic do away with the necessity of later sprayings for these pests.

One of the insects for which arsenical washes are used in quantity is the codlin moth. The young grubs usually enter the fruit by way of the eye, so that the most obvious method of dealing with it is to poison the eye so that the first meal taken by the grub is also the last one. This is effected by spraying, usually with arsenate of lead, within a few weeks of the setting of the fruit, before the fruitlet turns downwards and the eye closes.

The only possible chance of anyone being affected by arsenic in English apples would be if one were to make a remarkably large meal of the eye parts of apples alone, so large a meal, in fact, that the resulting feeling of discomfort would more probably be due to eating too much than to the effect of any infinitesimal particle of arsenic that might possibly have been swallowed.

To sum up, I honestly do not believe there is the slightest risk of anyone being affected by arsenic in English apples, more specially as the core, eye and stalk end are not usually consumed. As for American apples, with them I am not so much concerned, but I am not afraid of being poisoned by consuming quantities of these, although, of course, I always prefer English fruit, not because of any arsenic scare, but on account of the much better flavour.

Now just a word or two about the preparation and use of these washes. In spite of all I have said about the harmlessness of arsenical sprays, I am always very careful when mixing them, and always keep the stuff under lock and key, for it is dangerous to leave about. It is always preferable to buy a proprietary arsenical wash than to attempt to mix it oneself. There are many good brands advertised in THE GARDEN, and of these I rely almost entirely on Voss' lead arsenic paste, which has always proved satisfactory with me.

A fine spray should be used, as we want a light covering over the whole of the tree, and always stop spraying before the fluid drips from the foliage.

In conclusion, I would add this warning. Where it is at all probable that other plants may be wetted by the spray, do not use lead arsenate. Therefore where fruit trees are undercropped with other crops, it is advisable, almost necessary, to rely on some such specific as Katakilla or one other of the many proprietary washes advertised in THE GARDEN.—N. D. H.

TWO NEW SHRUBS WORTHY OF NOTICE.

ABELIA GRÆBNERIANA.

SEVERAL new abelias have been introduced by Mr. Wilson during his explorations in China, and one, A. Græbneriana, is certainly worthy of becoming a popular shrub in gardens, owing to its decorative qualities.

The plant is a native of western Hupeh, where it grows in thickets at altitudes ranging from 2,500ft. to 5,000ft. In Europe, and particularly at the Verrières Arboretum, where it was received from Professor Sargent seven or eight years ago, it forms a rather dwarf shrub, 3ft. to 5ft. in height, of semi-compact habit, bearing rather small, deep green, ovate lanceolate foliage, slightly villous on the upper surface and glabrous, or nearly so, underneath.

In May-June the pretty flowers are produced, grouped, sometimes as many as seven to eight at the end of the annual twigs, three-quarters or four-fifths of an inch in length, the wide open corolla is of a pale pink colour, hairy in the interior and glabrous on the outside. The throat is of a conspicuous yellow orange tone. The extremities of the divisions pass gradually to a creamy white. The shrub is very floriferous and quite conspicuous when covered with its elegant, not unlike dipelta looking, flowers.

According to Mr. Wilson, the species is somewhat variable in foliage and also in flower in its native country. So far, it has proved quite hardy, although at the Arnold Arboretum (where the climate is rather severe), for some reason or other, it has disappeared. Still quite rare in cultivation, its wider distribution is, to my mind, only a question of its becoming sufficiently well known.

THE CLUSTERED BLOSSOMS OF ABELIA GRÆBNERIANA.

THE GRACEFUL FEATHERY FLOWERS OF SORBARIA ARBOREA GLABRATA.

At the Arnold Arboretum two other new Asiatic abelias can be seen and both do rather well. One, A. Zanderi attains 8ft. in diameter and as much in height; while the other, A. Engleriana, is also doing well, but the rather inconspicuous flowers of these do not render them especially useful from the garden point of view.

SPIRÆA (SORBARIA) ARBOREA GLABRATA.

Another of Wilson's introductions, this beautiful sorbaria is distinguished by its very great vigour, its extra fine foliage and abnormally large racemes of flowers. At Verrières, we have several times measured plants 10ft. to 12ft. high and racemes 3ft. in length. When covered with flowers it is quite a remarkable sight. The flowers are pure white and the inflorescences exceedingly light and graceful. Although botanically a form of S. arborea, it is, speaking from a purely decorative point of view, a distinct and far superior plant altogether. In fact, of all the sorbarias that I know, this is by far and away the most striking, leaving all the other species and forms far behind. It is to be seen in many places on different continents and everywhere it is a conspicuous subject.

Sorbaria arborea glabrata deserves to be propagated freely, and this can be easily done as it seeds readily and suckers freely.—CH. LERAY.

INTERESTING EARLY FLOWERS.

THE dentarias are interesting early flowers, which seem to grow almost anywhere, but prefer a moist, sheltered spot in the woodland. They are known by the common name of "crinkleroot," as they have a curious notched, crinkly rootstock. Dentaria diphylla commenced to bloom here on March 2nd. It has broad leaves with soft pink flowers about 15ins. high. Another species, D. lacinata, is white and much taller than the above. They are easily propagated by root division, and belong to the mustard family. Dentarias prove a welcome addition to early spring flowers. The above species come from Canada, where they revel in moist woods.—R. MOORE, *Thorpe Hall.*

HARDY HEATHS

IN ALL GARDENS, BOTH LARGE AND SMALL, AT LEAST A CORNER SHOULD BE GIVEN OVER TO THE GROWING OF A FEW CHOICE HARDY HEATHS. THEY ARE INVALUABLE IN THE ROCK GARDEN AND IN THE WILD GARDEN, WHILE THEY ARE MOST EFFECTIVE WHEN PLANTED IN BOLD CLUMPS IN SHRUBBERY BORDERS, OR EVEN USED IN BEDS OF FORMAL GARDENS. DWARF VARIETIES LEND THEMSELVES TO MAKING ATTRACTIVE EDGINGS, WHILE THE TALLER KINDS LOOK WELL IN HEDGE FORMATION.

THE colour range in the hardy heaths is not remarkable when brought into comparison with some other families of garden plants, and even differences of form are of a character which frequently calls for close examination in order fully to appreciate their significance.

Nevertheless, the hardy members of the erica tribe are plants of unique charm, powerful appeal and unquestionable importance, and it may be contended with some justification that good collections, or even colonies, of what may be described as leading kinds should be far more generally established than they are throughout British gardens. Acquaintance with the nursery trade extending over a considerable number of years enables one to state that vast quantities of hardy ericas have been propagated in nurseries and have been sold, and one is driven to the conclusion that a very considerable proportion of that distributed stock has failed to establish itself in its new quarters. Prompt reply to the query "Why?" will generally attribute mortality to lime in the soil, but it is an assumption that must not be too readily accepted as a full and satisfactory answer to the question. In the first place some few kinds of hardy heaths do not share the accredited antipathy to lime which, admittedly, the majority do. Furthermore, there is a very great deal of lime-free soil in British gardens, as evidenced by the flourishing condition of many other lime-resenting plants. Still further, it may be maintained that failure to establish heaths has on various occasions, been witnessed in gardens where azaleas, andromedas and other plants which equally dislike lime flourish in a highly satisfactory manner.

In search of other causes of failure, one is drawn to the conclusion that a prevalent cause is the habit of demanding big clumps, in order to produce immediate effect. The nurseryman, in order to cater for the demand for big clumps, is driven to resort to division as a rapid means of propagation; but it would be surprising if any experienced plantsman should assert that such stock can be as satisfactorily established as plants propagated from cuttings and grown on for sale in pots. The side growths of ericas which are used for propagation are very tiny, and at best only a small plant can be produced from a cutting in a couple of years. Nevertheless, it would be infinitely more satisfactory in the long run to plant these small pot plants, which commence to grow without a check and make substantial headway during the period the coarser roots of old plants will be vacillating between effort and inaction. It would be incorrect to represent that no ericas can be successfully lifted and transplanted, for if the precaution is taken to bend down the outer branches, either weighting them with stones or securing them with pegs and then burying the bare wood in a mixture of sandy peat, these stems will emit young roots which will be more useful feeders than the tough old roots below. It is a mistake simply to get the old root beneath the surface and leave all the bare stems above the ground line.

Where soil is known to contain lime the selection of heathers should be among the varieties of EE. carnea, australis and mediterranea, including the various interesting hybrids among the last named.

Of Erica carnea alone a dozen good varieties are available, and, although several of these are of very similar shades of pink, the flowering season may be considerably prolonged by planting the greater portion of the series. Of course, E. carnea alba provides relief from the prevailing pink, and a comparatively new variety named King George is quite a deep red. This was flowering gaily in Messrs. Wallace and Co.'s nursery on the occasion of a mid-February visit. Messrs. Maxwell and Beale have been showing E. c. Vivelli, which makes a wonderful bit of winter colour, the foliage assuming bronzy red tints, while the flowers are bright carmine.

Of the mediterranea class the hybrid darleyensis is a delightful winter-blooming heath; and of unusual freedom is the white-flowered E. mediterranea alba; while hibernica Brightness is of a cheery, warm-tinted pink.

Still another idea occurs to mind regarding possible cause of failure to establish heaths in a satisfactory manner, and it concerns the method of introducing peat to soils of a more or less stubborn, tenacious character.

One has frequently seen basin-like excavations made in stiff, unyielding soil into which chunks of peat have been placed for the reception of the ericas. These basins are quickly saturated in wet weather, and are dried right out by a brief spell of drought. The spongy nature of the peat is responsible for excessive expansion and contraction as the mass becomes alternately soaked and dried, and such an unstable medium is detrimental to satisfactory rooting. An infinitely better plan is to trench the soil, work in some porous rubble with the subsoil, and mix the peat with some more solid but lime-free soil for the top spit, exposing the whole to a winter's frosts in order to make it friable and capable of being thoroughly well mixed.

Ericas from pots may be transplanted whenever soil is in a good, workable condition. March and April are good months for lifting from the open, but there is much to be said for the prudence of planting the different species and their varieties just as their flowering season ends.

SOME ADVANTAGES OF POT GROWN ROSES

THE ardent rosarian will not be satisfied in having blooms of his favourites from June to October, but he will desire to have some pot-grown plants so that he may enjoy the sight of beautiful roses during March, April and May.

The superb specimens exhibited at the Spring Show of the National Rose Society are evidence of what may be accomplished by the skilled amateur: and there is a growing number of amateurs who try their hands at pot-rose culture who do not attempt exhibiting for prizes.

Both Mr. E. J. Holland and Mr. Hammond, keen amateur growers of pot-roses, have exhibited specimens that have never been equalled at the summer shows. These gentlemen are really skilled hands at pot-rose culture; but any amateur who will just give the matter his earnest attention can in time produce fine specimens.

One of the secrets of success is to have good strong plants, well established in their pots. It is useless to attempt to grow pot roses unless they have good healthy roots and are potted up into good loamy soil.

Another important detail is to leave the plants undisturbed at the root for a few years. Each autumn the plants receive a top-dressing with some good fertiliser, such as Clay's, and have the drainage made good. Beyond this nothing is done in the way of disturbing them.

Of course, hard pruning is essential to obtain fine large specimen flowers. But pot roses are useful for those who do not care to exhibit their blooms or plants.

What can be more delightful than to walk into a house in March or early April, when perhaps the wind is biting cold outside, and to see the lovely roses in bud and in bloom?

No one can be successful in pot-rose culture unless a structure can be devoted to them alone. I know climbing roses are often grown in the roof of a greenhouse of other subjects, but even in their case they are the better if the house is kept for roses and roses only.

In a general way the hybrid tea and pernetiana roses will be grown; but the rambler and polyantha roses may become quite useful for conservatory decoration.

It is a good plan to pot up a number of plants from the open ground early in October. Do not attempt to force them the first year; but if kept in cold pits during the winter and plunged in ashes outdoors for the summer, they are available for forcing the following spring.

An additional number should be potted up, as they come in useful to fill up gaps in the beds; or they may be used as bedding plants where bulbs have been. It is unnecessary to turn them out of their pots, but simply plunge them in the beds and, of course, pay attention to their watering. The same plants may then be utilised next winter for forcing.

Any reader desirous of having some plants to bloom in May and early June can purchase prepared plants from most of the large rose growers. If such are pruned hard and put into a temperature of 45° Fahr. at night and 50° to 55° Fahr. by day, increasing to 60° to 65° as growth advances, they would have plants in bloom before the outdoor roses, but it would need to be done at once.

Another advantage of pot-grown roses is that they can be planted to fill gaps when it is too late to plant roses from the open ground; but unless they are sturdy, well grown plants, not much can be expected from them this summer.

Standard roses grown in pots form very beautiful subjects for conservatory decoration, and they are quite easily handled, and will soon develop glorious heads. Standards on the rugosa stock are by far the best for this purpose, as they have such an abundance of fibrous roots. Visitors to Chelsea may see such trees, and I would counsel them to observe those on rugosa stock and those on the briar.

The same may be said of the polyantha roses on short standards. They form delightful objects, very useful for decoration.

WALTER EASLEA.

BENEFICIAL INSECTS

IN every garden there are hundreds of insects which are in no way harmful, but help to rid the plants of various pests. Among these beneficial insects, the rove beetle, ground beetle, ladybird, lacewing or golden eye, and the hover fly take prominent places. Ichneumon flies, which lay their eggs in the bodies of caterpillars (frequently in such species as eat and spoil vegetables), do much to help the gardener. The wasp and the robber fly also clear off some insect pests, but those first mentioned may especially be looked upon as the gardeners' allies, and should never be destroyed or disturbed.

The larvæ of the ladybird (coccinellidæ), feed greedily upon aphides and scale insects (coccidæ). Therefore, when hundreds of ladybirds arrive at maturity it must mean that many thousands of aphides have been consumed in nourishing them; and since in case of an aphis shortage the incipient ladybirds have no hesitation in sating their appetites on members of their own family when they are hungry, the ratio of the numbers of ladybirds to those of available aphides is remarkably soon adjusted.

Although the ladybird is well known for its beauty, comparatively few people recognise its larva. This is black or very dark grey, developing some orange-red spots as it approaches maturity. It looks somewhat like a small reptile, with its rather prominent legs attached to the fore part of the oval body. The eggs have a waxy appearance, are creamy yellow in colour and stand upon their ends, in little groups, on leaves of currant and other bushes.

The lacewing (Chrysopa vulgaris) is also very beautiful, with its long neck and shining yellow eyes. Its green wings slightly resemble skeleton leaves and are set on the body in a graceful, sweeping line. The curious looking eggs are suspended on the ends of threads attached to the undersides of rose and other leaves. The larvæ are similar to those of the ladybird, and like them, live principally on aphides and scale insects. They have a strange habit of throwing the skins of their victims upon their own backs and allowing them to remain there.

The hemerobidæ are grey in colour, but of similar form and habits.

Most people will have noticed flies which appear to stand still in the air for several seconds above some leaf or flower. These are known as hover flies (syrphus), and in their larval stage are exceedingly useful for their ravages among the aphides and like pests. The appearance of these larvæ is not attractive, for they are rather slug-like and show little trace of formation, except that the head is narrow and the body gradually widens from the neck backwards. When feeding, the head is held up, away from the leaf on which the creature is sitting, while the victim's juices are being assimilated. The appetite of these larvæ is enormous.

Ichneumon flies (ichneumonidæ), have very slender waists, but are otherwise much like the common saw flies, which lay their eggs on our gooseberry bushes, thus providing that host of sticky green caterpillars. The reproduction of the ichneumon fly is very different. Each species of this fly is attracted to certain kinds of caterpillars, which it uses as nursing homes for its offspring. With a sharp-pointed ovipositor it inserts one or more eggs into the body of the caterpillar, in which the eggs hatch and the larvæ grow until ready to pupate. The caterpillar does not eat less because it carries its uninvited guests; but it can never hatch into butterfly, moth or fly, in order to continue the species; on the contrary, each ichneumon pupa may provide another enemy to the caterpillars. This is not always the case, however, for certain other species of ichneumon actually reach the larva of the ichneumon which is already hidden in the body of the caterpillar, by means of their ovipositors, and in it place their egg, which hatches and matures as does the one first deposited in the caterpillar. In spite of this the ichneumon must be regarded as an extremely useful ally and one which is well worth while recognising and preserving.

The robber fly (asilidæ) is a hairy insect that in its perfect form preys upon other insects and so assists in diminishing some of our pests and also merits preservation.

Wasps also do good work in the same way, but counterbalance it by their habit of fruit spoiling.

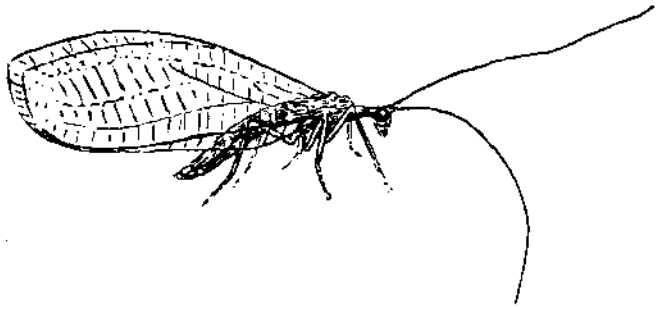
1.—THE ROBBER FLY.



2.—THE LACEWING FLY.

3.—THE HOVER FLY.

The rove beetle (Ocypus olens), better known perhaps as the Devil's Coachhorse, is a true friend, continually appeasing its appetite on small insects, which are mostly inimical to the interests of the gardener. This is a repulsive looking creature, with an aggressive habit of turning up its tail when touched, that is rather alarming to a stranger, but in spite of its scorpion mimicry it has no sting and may be handled with impunity.

The tiger beetles (cicindelidæ) and their near relatives, the ground beetles (carabidæ), are equally useful in the same way, and should not be destroyed. They may be known, roughly, by their handsome bodies, long legs and active habits, but it is quite worth while to take some trouble to visit a museum and learn to recognise these families with certainty.

In distinguishing carnivorous from herbivorous beetles, it should be borne in mind that those creatures which prey upon their fellows are likely to have stronger limbs and more intelligence with which to pursue their hunting than is needed by those which merely feed upon vegetation.

The illustrations of these insects have been enlarged (in order to show details) to about twice their natural size. All the characteristics of our three main insect friends may be thus clearly recognised.

M. L. BROOKE.

THE SCOPE OF THE GARDEN FRAME

IS FULL ADVANTAGE TAKEN OF ITS POSSIBILITIES?

FOR most well equipped gardens there is generally a good stock of frames, either the portable wooden frame or the permanent brick heated frame. But how often does one go round some of these very fortunate gardens, and see row after row of frames standing empty? On the other hand, where they are used, are they suitably placed to save labour in shading, and conveniently placed near the water tank, so that the plants they contain will not suffer for want of water?

I passed through one of the finest equipped gardens in the district not very long ago, and was very much interested in the frame section, especially in seeing frame after frame standing empty, and the few that were occupied covered up with heavy shading mats to keep out the strong rays of the midday sun. Not only was this causing a great deal of extra labour in shading, but on looking into these frames I discovered subjects that would have been happier if they had full advantage of the light or been placed in frames with a different exposure.

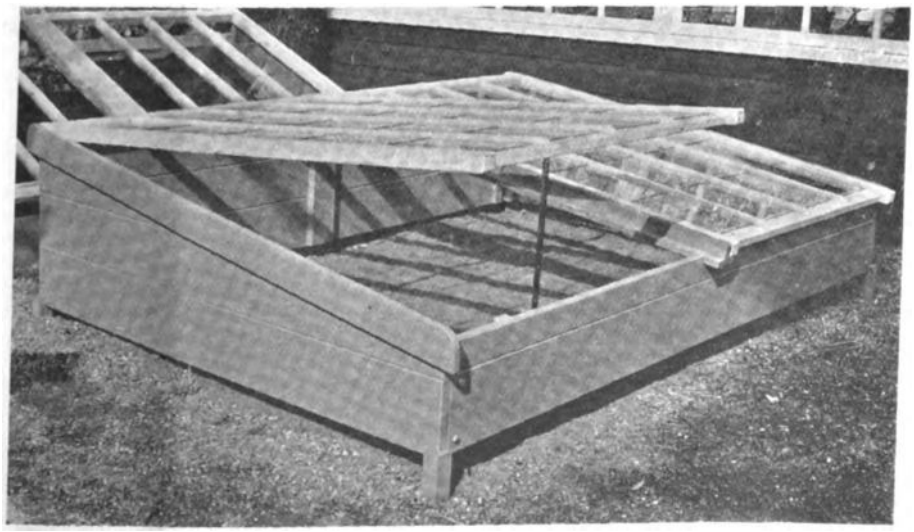
I will adhere strictly to the portable wooden frame, as this, if of a convenient size, can be moved about to the required site best suited to the class of plants it is to contain. It is mostly during the months of April and May that these frames are used, principally for the use of bedding plants.

Frames, when empty and well cleaned are far superior to the greenhouse for the growing of pot plants during the summer months. Yet, how often do we go round some of our great gardens and see greenhouse after greenhouse packed with subjects horribly out of place there which would have been more at home in the garden frame, and would then have left the greenhouse free for more useful plants, such as the tomato.

Undoubtedly, cinerarias, cyclamen, calceolarias and primulas are quite at home in a garden frame during the summer months. But what is more detrimental to their growth than to be placed in a frame facing due south where it gets the full blaze of the sun and has to be covered up with heavy shading mats? Not only does this entail extra labour and create a very high temperature, but it also causes the plants to become drawn and subject to the attacks of green fly. Whereas, if the frame in which they are to be grown were placed behind a wall or hedge facing north, they would need no shading, less watering, and have that nice cool atmosphere so essential to this class of plant.

At the end of the summer months, when all the plants are removed from the frames to the greenhouse, the frames may again stand empty until the following spring; whereas every one should be used to full advantage for various purposes.

First, in the garden there may be a plot of parsley which, if exposed to the elements during the winter, would be completely lost, but protected by a frame it will supply the house with good clean parsley during the dull days of winter and be much appreciated. Secondly, how often are we caught by early autumn frost? Perhaps for one night only, but just sufficient to cause great damage, especially to French beans. If a frame be at hand, however, it is a matter of a few minutes to place it over these if there is the least sign of frost, for with a little



A USEFUL PORTABLE FRAME.

Digitized by Google

forethought the beans could have been sown in such a way to allow of this being done, and so have a supply of beans well into the winter.

Some years ago I noticed a small outside border in front of a vinery planted with strawberry plants about six inches apart, the gardener told me he covered these with frames all winter and could, with a little care, pick strawberries about the end of April; whereas in most places they are grown in specially heated houses, which means extra expense and a great deal of labour.

In most cases garden frames are treated as makeshifts; but they should receive the same care as the heated structures, for it is out of these makeshifts that most of our valuable pot plants come to adorn our heated structures during the dull days of winter; so, if these makeshifts are not kept clean, we cannot expect those nice clean plants which adorn our greenhouses. All that is required is a wash down with soap and water in the inside, and the glass wiped down with a cloth—for how often does one see the glass in frames covered with green slime which no light will ever penetrate?

Pages could be written on the various ways in which frames could be used to better advantage when, most of the time, they are lying idle and being neglected; but space will not permit.

JACK LONDON.

FUNGICIDES FOR PRESENT USE

IN the constant warfare against the enemies of plant life fungicides are of equal importance with insecticides, but there appears to be a greater readiness on the part of writers to deal with insecticides than with fungicides, and of that which is written regarding the latter a large proportion is in a highly scientific strain which mystifies rather than helps the average gardener or garden owner.

Diseases are essentially more difficult to deal with than insect or animal pests. These latter are for the most part easily discernible even if sometimes difficult to identify, but diseases—and most plant diseases are of a fungoid or parasitical nature—are frequently invisible to the naked eye until they have made so much progress that serious damage is done and cure is rendered extremely difficult, if not practically impossible. It may be taken as a general rule that a fungus in an advanced stage of activity has gained a foothold in the cellular tissues of its victim, and that, in consequence, anything which is strong enough to kill the fungus in its active stage will either kill or seriously injure the plant. True, some fungoid diseases may be held considerably in check by means of applications of various chemical preparations applied after the disease has established itself, but in the long run it is far more effective to adopt preventive rather than curative measures.

Winter spraying of hardy fruits is generally advocated, and chiefly in connection with fungoid diseases; partly because more powerful chemicals may be used while trees are leafless, but also because many of the diseases are more vulnerable in winter than during summer activity.

The same thing applies to diseases of grape vines and various other subjects under glass, and it would be of untold benefit to rosarians if the doctrine were widely preached that common mildew of roses may be more effectively dealt with during late autumn and winter than when foliage begins to whiten in summer.

Fungicides may be conveniently, although somewhat loosely, divided into several more or less independent groups. There are simple, harmless, non-poisonous fungicides which are useful up to a point, and may be used with no great risk by inexperienced hands at most seasons of the year and on most kinds of plants. There are also powerful poisons which are so effective against very serious diseases that, despite the necessity for the exercise of extreme care in handling, they must rank among the essential equipment of every extensive garden.

Fungicides for summer and for winter use, for outdoors and under glass, dry powders and liquids, all constitute groups of considerable importance, and there are numerous proprietary articles or mixtures on the market which may worthily be termed combined fungicides and insecticides.

For our present purpose it may probably be of greatest service to deal first with the simplest and safest fungicides, having regard to the fact that the season is too far advanced for the present use of the more powerful mixtures such as can be used to great advantage on dormant trees and plants.

FLOWERS OF SULPHUR.

In its dry, powdered state this familiar article is very largely used as a cure for mildew on roses, delphiniums and various outdoor subjects, and upon grape vines and many other plants under glass. Faith in its powers is frequently greater than can be justified by actual demonstration, and it would be correct to say that dry flowers of sulphur or flour of sulphur, as it may more appropriately be called, is somewhat overrated. Nevertheless, if it is carefully applied in good time, it is capable of checking the development of the common mildews, and it has the distinct advantage of being harmless ammunition for the veriest novice to use. It is essential that the sulphur shall be of high quality, perfectly "sublimed," as technical language has it, to form the finest of flour-like powders. Dry sulphur frequently fails to reach its maximum efficiency through defective application. The ordinary dredger-topped rubber puffs deposit the powder in separated hillocks, and the small hand bellows eject it in irregular jets. The real need is to coat over every particle of a plant with a perfectly even but extremely thin covering of sulphur. Powder machines of considerable size are available which are capable of good work on large, dense plantations, such as nursery quarters of young trees, fields of potatoes, etc., but it is a difficult matter to secure an equally smooth discharge on a small enough scale to enable an isolated rose bush or delphinium to be covered without also scattering a vast quantity of sulphur over the soil and still more before the wind. Powder spraying is not confined to the use of sulphur, but it is not at present of equal standing with liquid spraying; to bring it into widespread general use it is very essential that attention shall be directed to the improvement of *small* distributors for private garden use.

LIME-SULPHUR SPRAYS.

Whatever may be the correctly estimated value of sulphur as an independent fungicide, it is of still greater service as an ingredient of compounds or mixtures of lime and sulphur to form a liquid spray. It must be admitted that some practical men consider lime-sulphur spray of small account, the usual criticism being that it is variable and unreliable. When such complaints have been closely investigated it has generally been found that the spray has been home-made according to formulæ which have been published in many books and pamphlets. The difficulty is that, although it is a simple matter to weigh specific quantities of both lime and sulphur, and to measure very accurately the water in which the ingredients are boiled, it is by no means so easy for the horticulturist to ascertain the precise strength or caustic power of his lime or the purity and solubility of his sulphur, and upon this, together with analysis of the water used, depends the efficiency of the spray.

It is a perfectly reasonable proposition that well known manufacturing chemists are able to ensure that the preparations they send out to face the competition of the open market shall be of highest grade and uniform strength, and with the numerous brands of lime-sulphur spray which are readily available it seems a pity to risk failure for the sake of the small economy effected by making home-made mixtures of doubtful quality.

Lime-sulphur has proved effective against mildew of most kinds, apple and pear scab, hollyhock rust and various leaf-spot diseases, for which its use is generally recommended during spring, when spores are liberated and blown about by winds to find lodgment upon young foliage.

The spray, however, is of even greater use in February, when it will prevent birds picking out fruit-buds from both tree and bush fruits. Furthermore, it will at this season do good service by suffocating the first hatchings of aphis, and being a very harmless spray it may be strongly recommended as one that should have a place in the annual spraying calendar, and which combines the fungicidal properties with the other powers mentioned.

L. I. ATRIS.

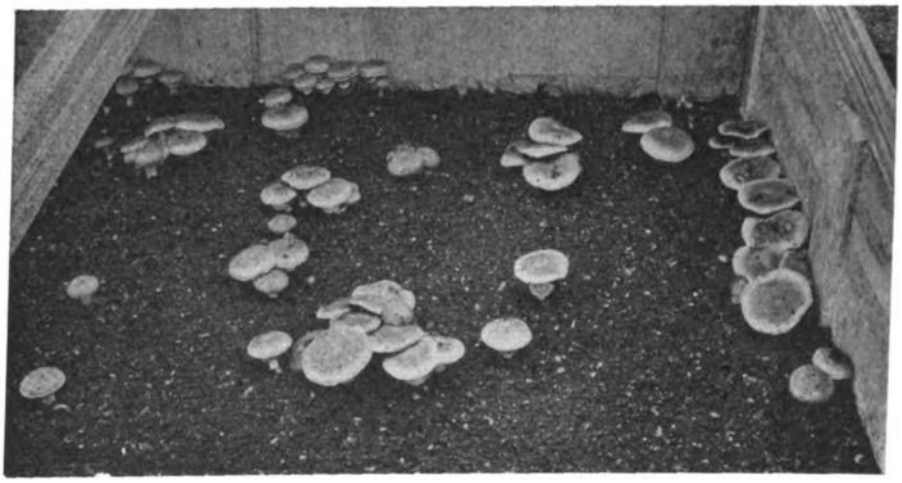
HINTS on MUSHROOM CULTURE

THERE is no great mystery connected with mushroom culture, providing a few simple details are observed. Two things are essential, a quantity of horse droppings from animals fed on dry food, and reliable mushroom spawn. The latter is bought in cakes, or bricks, and should be obtained from a reliable source, where they have quick sales, otherwise the mycelium of the mushroom may have perished before it reaches the grower. The droppings from horses fed on grass or roots are of little value, and if at any time the animals are given medicine, it will be advisable to discard the droppings until things are again normal. Collect the droppings daily, and store them on the floor of an open shed, free from drip and rain, and turn them over twice or thrice a week, at the same time forking out all the long straw. This should continue until sufficient manure has been collected to make up a bed, and operations can begin with two or three cart loads. Before the bed is constructed, it will be necessary to form a long heap of the manure and turn it several times, say every day for a week. At each turning the sides of the heap must be worked into the centre, then it will heat or ferment and in seven or eight days all the rankness of the manure will be eradicated, and the whole sweetened. When ready the droppings will be dark in colour, neither wet nor really dry, a condition that can be ascertained by taking a handful and pressing it. If it is cohesive, without losing any of its moisture, it is ready for making into a bed.

Where there is no proper mushroom house (and these are often a failure), select a dark shed, a frame, or an old stable—a cellar is also suitable, where it is easy of access; but the enthusiastic grower will find some building wherein a bed can be made. During the spring and summer months a little spawn inserted in the cucumber frame is often a success, while I have also had a fair crop on the asparagus beds from spawn planted in April. Darkness is essential, especially when growing them inside. The size of the bed will depend upon the quantity of material available, but the depth varies very little. The back should be about 20ins. deep, with a gradual slope to the front, which ought to be say 1ft. in depth. Make the manure quite firm, and in a few days it will generate considerable heat. A hot-bed thermometer is well-nigh indispensable for the beginner, and when this falls to 80° the bed should be spawned. The bricks are broken up into pieces about the size of a hen's egg, inserted 2ins. deep and about 8ins. or 9ins. apart all over the bed. A small hand fork is useful for planting the spawn, and care should be taken to bring the manure close to the spawn to prevent any hollow spaces. Level the bed with the back of a spade or shovel, and after a few days it should be covered with a 2in. layer of virgin loam, and gently pressed down with the back of the spade. No water will be needed until the crop appears, and when moisture is needed it must be tepid, and given through a fine-rosed can. The temperature in the shed for a start should be about 60°, but when the bed is bearing, 10° lower will do no harm. A few barrow loads of fermenting material will help to keep up the requisite temperature, and if the atmosphere is on the dry side, steps must be taken to counteract this by syringing the sides and floor of the building with tepid water. Mushrooms enjoy a moist atmosphere, and an equable temperature.

The period between spawning and cropping is from six to eight weeks, but I have had beds spawned in the autumn lie dormant till the following spring when a good crop has been gathered.



MUSHROOMS ON A HOT BED.

How long the bed will continue to be profitable depends largely on how it was prepared, but when it begins to show signs of exhaustion a handful of salt in four gallons of water will sometimes help it.

When gathering the mushrooms, take care that the root comes out with the stem. The old practice of cutting is obsolete, as the portion of stem left in the bed is detrimental rather than otherwise. Woodlice are occasionally present, but can be trapped with flower pots partly filled with moss, and laid on their sides.

The procedure is much the same for beds in the open, except that they are slightly different in shape. The bed should have a base of 4ft. or 4½ft., and be gradually built up to a foot in width when it is finished off. When completed it will be similar to the roof of a house, and it is spawned at the same temperature and in a similar way to other beds. Cover them with a good layer of clean straw, and then make it secure from rough winds. Hurdles, or mats, will be suitable for this purpose. T. W. BRISCOE.

CORRESPONDENCE

PLANTS FROM SEED.

SIR,—Perhaps in all the variety of garden work there is nothing of such absorbing interest as raising—or attempting to raise—plants of every sort from seed. I am not thinking now of the hardy annuals which, as a matter of course, we sow for the adornment of our gardens, but rather of perennials, alpines, bulbs, shrubs and even trees. THE GARDEN has done well from time to time to give instruction in this art. In the issue before me (January 16th), there are two useful articles about it, one of detailed instructions for raising various perennials and the other about the treatment of seeds of shrubs and trees, and I cherish a set of old numbers (to wit, those of December 24th, 1921, July 1st and 15th, August 12th, and December 23rd and 30th, 1922, and August 18th and December 15th, 1923), which give much help and many hints. In particular the table, "When and How to Sow," in the number of August 18th, 1923, has proved valuable. Seeds are, however, not only, like Cleopatra, of infinite variety, they are of infinite vagary as well. The seed-pot has always hope at the bottom. If I venture to give some notes on my own successes—we will take the much more numerous failures for granted—it is because I would pass on the experience to other amateurs.

First, where are we to get our seeds outside the usual run of florists' flowers? Everybody of course knows the catalogue of Messrs. Thompson and Morgan, of Ipswich. Other lists, not so extensive, but in some cases specialist, are issued by Messrs. Barr, Messrs. Wallace of Tunbridge Wells (many lilies), Messrs. Perry of Enfield (many bulbous plants), Mr. W. E. Th. Ingwersen of Sharpthorne, Mr. J. F. Anderson of Glenn Hall, Leicester, and Messrs. Clarence Elliott, Limited, of Stevenage. M. Henry Correvon, of Floraire, Chêne-Bourg, Geneva, has an enormous list of seeds of alpines and perennials, many unobtainable elsewhere. Messrs. E. and W. Hackett will send you from Adelaide a list of seeds of Australian native plants, and Messrs. Starke and Ayres of Cape Town a list of those of South Africa. And for South African seeds you can become a Member or Associate of the National Botanic Gardens at Kirstenbosch, which issues yearly a list of seeds for distribution. From the Chandra Nursery, Rhenock Sikkim, Bengal, you can obtain some Indian seeds. And Messrs. Vilmorin-Andrieux et Cie, 4, Quai de la Mégisserie, Paris, will send you catalogues (ask for the catalogue of seeds of greenhouse trees and shrubs, as well as the catalogue of hardy ones), which will open to you possibilities of which you had not dreamt.

Digitized by Google

I have mentioned lilies and other bulbous plants. I should call these notably easy, though some of them are slow. Of the raising of lilies from seed a good deal has been written lately. Crinums seem to come readily from seed, though nowhere have I ever seen it offered. Scilla peruviana, babiana, watsonia, tigridia, Sparaxis pulcherrima (bad to transplant—sow *in situ*, or try one seed to a pot), Asphodeline lutea, Fritillaria Meleagris, muscari, brodiæa, are ventures of my own which have come up in the most heartening way. Indeed, I have had hardly any failures with bulbous plants so far as germination is concerned. The South African bulbs are surprisingly easy. Lilies do not come up in so high a proportion; or is it that the prowling slug too frequently scents that one vital first leaf from afar? For lilies I suggest that the soil on and under which they rest should be even grittier and lighter than that of their lower stratum, and I put them in edgeways, to avert rotting. In their case, and in the case of all seeds large enough to handle (as all those mentioned above), it is best to put them in individually at about an inch apart. This is more trouble than scattering, but it is worth it. Indeed, there is no reason why, say, tigridias, which come up practically every one, should not be sown in the pot in which they are to flower, and the seed spaced out in it with that in view.

Let me mention some other plants which I have raised—not always for keeps. Sesbania Tripetii, Rhodotypus kerrioides, Poinciana Gilliesii, indigofera, erythrina, hedychium, Strelitzia Reginæ, acacia, crowea, marianthus, boronia, mandevillea, libertia, Kniphofia rufa, Phlomis fruticosa, Cassia corymbosa, Commelina cœlestis, Æthiopappus pulcherrimus, sedum and sempervivum. Nelumbium fairly startled me. I obtained a packet of a dozen or so, and found them black, beanlike and hard. "These," I thought, "will take months to germinate, if they ever do." According to instructions I filed them lightly, and sowed them in pots which stood in pails of water in the open garden in summer. They were up in fourteen days! So the veriest amateur of us may make his attempts, though we should make them with intelligence and care, for these things of beauty with which we deal have their claim to existence and opportunity.

May I mention something which has occurred to me? The germinating seed requires air. Is it possible that when we cover smallish seeds with the compost which we have used to sow them on it becomes, when it subsequently has to be watered from above, a clog to their breathing? Should we not give them a better chance if our thin layer of covering soil was almost entirely a sandy grit?—W. R. J.

THE FIFTY BEST SAXIFRAGES.

SIR,—Saxifraga atropurpurea Stormonth's variety, of which Dr. R. Lloyd Praeger does not know the parentage, was raised here. It was a seedling noticed alongside its coloured parent, and, apparently, owing its paler colour and broader petal to a dwarf mossy white variety growing near. Several years after its appearance, there sprung to light S. Fergusoni in Dr. Ferguson's garden at Duns, N.B., and S. Guildford Seedling in Mr. H. Selfe Leonard's garden at Guildford. Both of these were noticed in the same season and apparently owed their colour to S. Rhei, which was grown by both these gentlemen.

ONE OF THE BEST TALLER GROWING RED SAXIFRAGES, S. DECIPIENS GRANDIFLORA.

I think we are indebted to Mr. G. Arends of Ronsdorf for the seeds, sent to this country, and from which S. decipiens grandiflora—the first and, perhaps, still one of the best of the larger growing reds—was raised at Bath by the late Mr. Kitley.—JOHN STORMONTH, *Kirkbride, by Carlisle.*

THE STAKING OF PLANTS.

SIR,—I often read in THE GARDEN of the various ways of staking plants in a border and so many people seem to suffer, as I did, before discovering my present very simple method, that I venture to describe it on the chance that it may be a help to someone. The soil here is a sandy peat, very light and in a high wind the ordinary bamboo merely pulls up and lies flat with the plant it is supposed to be supporting. Single bamboos, also, look hideous in my opinion, and still worse is the clump of phlox tied round its middle in a compact lump.

My plan is this, arrived at after many experiments. You get for each clump three bamboos, or in the case of taller plants, such as delphiniums, hazel sticks about 5ft. long. You push in these three sticks round your clump, neither more nor less will do, as far in as you can get them. Then tie the three tops together with tarred string as firmly as possible, about 3ins. or 4ins. from the top, forming a tripod. You then tie a stout string round the tripod about a foot from the ground. That is all. The plant grows up through the tripod, which supports it firmly and is quite invisible once the leaves are fully grown.

Sometimes in a wet summer I have put a second waistband farther up the stakes, but only now and again. The strongest winds do not shift the stakes tied in this way and at the end of the summer you can cut the string, pull up your stakes in a few moments before cutting down your plants for the winter.

I hope I am not teaching my grandmother a new method of eating eggs; very possibly I may be, but I confess I have not seen this plan in any other garden but ours. I see someone enquires why peonies are not so popular as roses. In my case it is because the price is usually too high. I mourn the fact because roses are not happy here and peonies flourish. The other drawback is the lack of scent. Only a few seem to be scented.

May I add a P.S. to the praises of rosemary. Rosemary: a culinary hint.—A small spray of rosemary put beneath the Sunday joint before it goes into the oven, is the greatest improvement to a dull leg of mutton or round of beef. It is best with mutton and gives a delightful flavour to the gravy.—NORA ELOART, *Devon.*

RED SAGE.

SIR,—With regard to my article in THE GARDEN of January 2nd, on "Red Sage," I did not in the least mean that I thought Bergamot Pear and Monarda fistulosa were one and the same thing. What I wrote was in answer to your correspondent's query as to what was the "Red Sage," which possesses medicinal virtues. Monarda fistulosa, which, like Salvia officinalis, belongs to the labiates, is known in many country districts in Britain as either bergamot or red sage and is classed among medicinal plants. In the Midlands the peasants call monarda sometimes by one of these names and sometimes by the other. Its popular name in France is Sange rouge. The name red sage is not meant to imply that the plant is a salvia, any more than its popular name of bergamot, that it is the bergamot orange or the pear of that name. Neither of these names is, of course, scientifically correct. They are the popular ones used in local parlance.

I regret very much indeed and offer my very humble apologies to our seedsmen for the misleading statement I made with regard to Didiscus cœruleus. I ought, of course, to have stated that, as I had never come across it in Britain, I concluded that it was not very well known there.—VICTORIA SLADE. *Hautes-Pyrénées, France.*

A SELECTION OF POTATOES.

SIR,—Mr. Norman Lambert's article on selection of potatoes in THE GARDEN, March 20th, prompts me to ask why one variety is mentioned twice, namely, Duke of York. The National Institute of Agricultural Botany and the Board of Agriculture for Scotland have at their trial stations proved beyond any doubt that Duke of York and Midlothian Early are synonymous, and that the correct name for this splendid first-early variety is Duke of York.

I have grown Midlothian Early, The Duke and Victory, to mention but a few names, and so far could find no botanical difference between them and the Duke of York. It is a great surprise to me that so many people duplicate their varieties of potatoes. What if the same thing happened with varieties of apples, etc.? What a hopeless muddle we would get into.

The Potato Synonym Committee is doing splendid work, but still many people grow

Digitized by Google

varieties under different names. It must be admitted that if we take a variety and compare it with a standard type and it is indistinguishable in its botanical characteristics, then they are synonymous. Why, then, hamper that standard type with so many names?

If we are to take Mr. Lambert's selection of first-early varieties and order, say, 1cwt. of Duke of York and 1cwt. of Midlothian Early, would we not get them supplied by the seedsman out of the same pit? Then why not order 2cwt. of Duke of York and save all this confusion?—GEO. STUART, *Edinburgh*.

GARDEN TECHNIQUE

FLOWER GARDEN

POLYANTHUSES FOR NEXT YEAR.

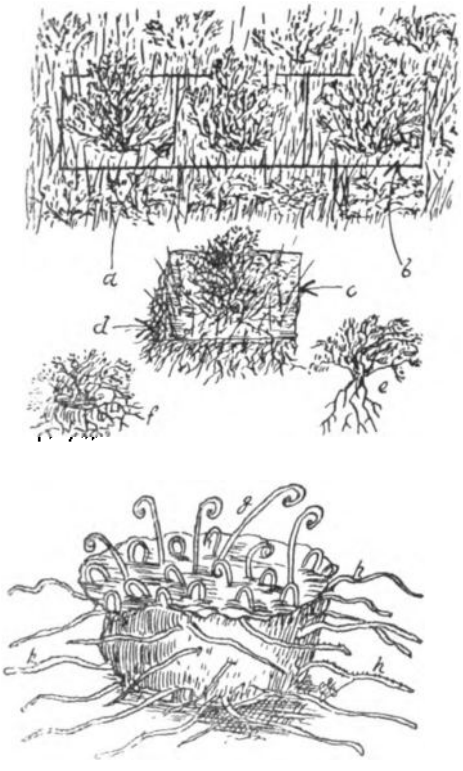
IT may seem a very early date on which to talk about polyanthuses for 1927. But all experienced cultivators know, already, how very important it is to have early stock if success is to be achieved. These notes will, therefore, be helpful to beginners who wish to have fine displays as early as possible in the spring. Do not grow a poor strain, grow the best obtainable. Even the poorest flowers, I admit, possess some individual beauty, but those of the best strains are exquisitely beautiful. Like our greenhouse primulas, the seeds of the polyanthus germinate irregularly, so that it is advisable to sow them thinly and to wait patiently for the laggards to appear in tiny plant form. I advise the use of flower pots or pans for raising seedlings where a few plants only are required, but boxes may be used and especially for large numbers, as ample room should be allowed for the young seedlings, owing to the fact that some of them must be lifted and transplanted before others are forward enough for removal. The polyanthus is a plant that thrives best in a cool temperature and fails if subjected to a very dry soil and arid atmosphere; therefore, provide cool quarters for both the seedlings and the growing plants in the summer. Place the seed vessels in a cold frame, fill them with good loam and a small proportion of rotted leaf-soil. Sow the seeds thinly and cover them an eighth of an inch deep. Keep the vessels in darkness until the first few seedlings appear, then gradually expose them to the light, but shade from bright sunshine. Transplant with care, once prior to planting them in their summer quarters, which should be on cool borders and in a medium rich soil.—CHRISTCHURCH.

COLUMBINES.

NO one who values these quaint and beautiful blossoms would dream, when sowing seed or adding to their stock of plants, of leaving out of their purview the popular long-spurred varieties; yet, I sometimes imagine, in their desire to grow the latest modern sorts, many overlook the older and beautiful forms as represented by Aquilegia vulgaris. Some firms appear to have dropped the latter altogether and content themselves with pushing the long-spurred sorts, but I venture to say the common species of vulgaris, which give an abundance of short-spurred flowers of purple and blue and red and white, are worthy of culture. It is admitted that the older forms are stiffer in build and lack that "airy lightness" which characterises the long-spurred; yet who shall say that, seen in groups about a garden, they lack charm? It is well known that columbines last a long time as cut flowers for table decoration, and equally is it admitted that nothing further is needed to enhance them than their own foliage. I find it best when making a sowing of seed in May or June to do so in a cold frame, using a generous compost made up of loam, leaf-mould and old manure, with sand added. Even after a winter like the past, one comes across "self sowings" in the borders, and it is not, therefore, necessary to resort to sowing seed every year. Perhaps most of us associate these old-fashioned garden plants with sunny places, but if one desires the longest display, a partially shaded position will be found the best. They do well, so treated.—CLAREMONT.

WILD HEATHER AND BRACKEN FERN.

WHEN one sees the heather growing wild on the common and the bracken fern beside it or fringing the near-by wood, carpeting acres of woodland or clothing the rough bank with beautiful, graceful green foliage, one wishes a few patches could be transferred bodily to one's own far-off garden. Sometimes it is found desirable to shift clumps growing in the garden to another



position. I have lived among hundreds of acres of these plants for nearly fifty years and have transplanted them with much success. Clumps may be lifted and transplated at any time now. But the positions should be duly prepared for them beforehand, and, if the soil is all stiff loam, add small stones and peat, packing the latter round each clump as well as making of them a nice firm bed for the clumps to rest on. Wild heather may be found thriving on a very dry bank, but if the clumps are disturbed while in that condition most of them will die, because it is so difficult to get the soil and roots moistened again when they are surrounded by loose compost. Therefore, water the soil thoroughly before the clumps of heather are lifted. Lift large clumps, cut across between them, as shown at *a*, and then all round, as shown at *b*. Use a spade for this work, and leave a smooth edge at the top, *c*; but roots well drawn out of the lower soil, *d*, by the aid of a garden fork. Plants lifted as shown at *e* will probably die; but small ones lifted as shown at will live. Bracken fern with fronds growing as shown at *g* may be safely lifted in clumps if the rhizomes, *h*, *h*, *h*, are carefully preserved. Plant all firmly, water and shade for a time.—GEORGE GARNER.

VEGETABLE GARDEN

FORMING AND PLANTING A HERB GARDEN.

IN many cases, not in all, I admit, the herb borders are made in unsuitable quarters in the garden and the plants are neglected. Many kinds of herbs can be raised from seeds; a few, such as chives, tarragon, lemon thyme and mint, are raised by root division. Plants, resultant from seeds, are generally strong and stocky of growth, consequently a good stock of herbs is soon ready for harvesting. The position of the herb garden should be an open one so that the plants will flower early and freely; the full strength of some kinds of herbs is reached when they are flowering and it is at this stage that they should be harvested. If the quarter selected is sheltered on the north and east sides it does not matter much about full exposure on the other sides. For general convenience in matters attendant on sowing, weeding and harvesting, the plants should be grown in rows in beds about 4ft. wide. The beds, being raised about 4ins., with alleys 18ins. wide between them. Parsley and kinds that are in most request should occupy whole beds, while several of those less frequently used may share one bed. Some seeds may be raised in boxes and the resultant seedlings duly transplanted in the herb garden. It may be advisable to have a special border in a more moist part of the garden for mint and angelica, as these two kinds thrive best in a moist rooting medium. This will be necessary only where the general soil for the herb border is a dry one. It should be rather a dry soil to suit the majority of herbs. The plants raised under glass should be finally planted out early in June. Seeds sown in open borders should be got in about the middle of April. A moderately rich soil is the best.—HANTS.

THE MAKING AND UTILISATION OF CELERY TRENCHES.

THE sooner the celery trenches are made the better. There is still a good deal of moisture in the earth at this season, and so the smoothing of the sides of the trenches is more easily accomplished now than later, when the earth is dry and crumbly.

Celery plants make numerous roots, and it is necessary if good plants are to be grown that rich material should be spread in the bottom of each trench. On very heavy soil, or where the situation is somewhat shaded by tall trees, it is not a good plan to make the trenches too deep. If the soil is excavated to the depth of 15ins. and banked up on either side in a neat and proper manner, the trenches will be quite deep enough should the soil below that depth be of a clayey nature. The cultivator should—if leaf-mould, old potting soil or farmyard manure is scarce or difficult to get—keep to one side a sufficient quantity of the surface soil while excavations are going on to make up and mix afterwards with the manure or other feeding matter, which should fill the bottom of each trench to the depth of 9ins., and on this the celery plants should be set when planting-time comes round. When the trenches are made they can be filled temporarily with bedding calceolarias; then wire pea trainers can be placed along the top, and thus a framework is made, over which frame mats can be spread in the evenings when frosts threaten.—D. ARMSTRONG.

MISCELLANEOUS

THE ONION FLY MAGGOT.

WHAT a source of constant trouble the onion fly maggot is to nearly every gardener, every year! And how many remedies have we all tried, some with success, some with only partial success and others—quite a large number—with only disappointment and a sparsely filled onion bed! There are such useful formulæ as paraffin emulsion, hellebore powder in water, paraffin and ashes, soot and lime and many others. But several years ago a friend of mine gave me a "tip," which has proved itself well worth trying.

For quite a number of years in succession, onion beds in the district where my friend was head gardener, had been badly pestered by the onion fly maggot. It was noticed in a very marked way, each year, that, while everybody apparently failed hopelessly to raise onions worthy of note—although, like honest gardeners, they had used every conceivable method of prevention and of cure—one man only seemed able to show a bed of onions worthy of the name. How was it done? He chose for his onion bed the previous year's celery trenches, levelled off, manured and re-dug. I pass it on!—ELSON.

DAMPING-OFF.

MOST gardeners are only too well aware of the disastrous effects of the trouble known as "damping-off." The happening is due to the attacks of a minute fungus which is able to make headway where there is an excessive amount of moisture in the atmosphere or soil. The effects are most marked among young and tender seedlings when these are crowded together or placed under unsuitable atmospheric conditions. A common cause of damping-off among seedlings is to be found when the temperature in a glass house or propagating frame is lower than that outside. This induces condensation of water on all parts of the plants as they become colder. Here, if it is possible to raise the temperature of the house, the moisture soon evaporates and is once more suspended in the air. Free ventilation, when the outdoor conditions make this possible, will often prevent and remove the excessive formation of moisture on the seedlings. Directly any signs of damping-off are to be seen, healthy seedlings should be transplanted and placed out singly in fresh soil. All affected specimens should be destroyed. The wisest course of all for the gardener is to bear in mind the conditions which lead up to the activities of the fungus. Much may be done to prevent the attack by providing ample drainage, a porous compost, and the exercise of great care in watering. Any watering should be done as early as possible in the day, so that, before nightfall, every trace of superfluous moisture has vanished.—L. B.

PRUNING PLUMBAGO AND BOUGAINVILLEA.

THESE plants, treated somewhat similarly to grape vine rods, look charming when in full flower under the roofs of lofty greenhouses and conservatories. In lower structures they look best treated as pillar plants or under the roof near the end of the house. Throughout the winter months the soil in which the plants grow should be kept almost wholly dry, but in spring it should be thoroughly saturated with clear water. Last autumn well managed plants would be pruned back to within 1ft. of the main rods. These side shoots or branches, which so much resemble the vine branches, should be pruned to within 1in. of the base of each. By the first week in April the young side shoots will be about 3ins. long, and by the middle of June or a little later, perhaps, the first flower-buds will form. From March to the middle of July the plants should be fed with weak doses of liquid manure twice every week. The flowering branches—all of them will not bear flowers—should be allowed to depend gracefully from the roof and not be tied in stiffly and formally. The appearance of these long, flower-laden shoots is very effective indeed. Heliotrope may be treated in a similar way, but the flowering branches must be carefully pulled down, as they naturally tend to grow upwards at first. When once a cultivator has judiciously furnished the roof of his lofty greenhouse with great masses of the flowers named, he will continue their cultivation, as the roof will rival the staging in the rich colours of the blossoms.—GEO. GARNER.

SPRING AND EARLY SUMMER TREATMENT OF AUTUMN-LAID TURVES.

IT is generally an advantage to lay turves before Christmas—October and November being the two best months for the work: then there are sure to be a good quantity of new roots available and permeating the soil below before the hot weather comes. Only in exceptional instances should turves be laid in late springtime. But in the case of autumn-laid ones it does not follow that they will form a perfect lawn, tennis court or bowling green without some close attention during the spring. Although the turves may be left in very good condition in the autumn, the weather that follows has a bad effect on them if it is frosty, and if very dry in spring uneven turves are difficult to get level again. Frosts loosen hard, undisturbed ground, and recently cut turves are sure to be displaced a little. Before the drying winds come, closely examine the ground, have a quantity of finely sifted soil in readiness, also some wood ashes; add a 6in. potful of the latter to each bushel of prepared soil. First fill up all open spaces found between the turves, then scatter 2 pecks per square rod, generally, on the turves, gently brush it all to and fro, working in the fine soil and ashes. Follow with the roller, doing all while the surface is fairly dry. Early in June apply 2 oz. of bone-meal per square yard, and a beautiful firm lawn of fine grasses will result. Do not use farmyard or other fresh organic manure.

PATCHING LAWNS.

TOWARDS the end of the winter unsightly bare patches on lawns are not uncommon. The writer has found that a very good way of repairing these is by means of grass mats formed in the following manner: Cut out a piece of sacking somewhat larger than the bare patch. Rest this on the floor of an outhouse where there is a certain amount of light. Sprinkle the sacking with water, and then, on the material, sow grass seed thickly. Naturally, if the grass mat is kept moist it is soon thick with green growth. One point should be borne in mind, and that is, if the grass mat is resting on soil it should be moved about every few days to prevent the roots getting a hold. On the whole, it is better to have the mat on a brick floor where there will be no possibility of any rooting. On any mild day, when the grass has grown well, the mat may be transferred to the patch on the lawn. Loosen the surface of the ground well and trim the mat with scissors to the correct shape. Then place it in position, pressing it down lightly. It will be found that, in good growing weather, the grass plants rapidly take root and render the repair a permanency. The sacking soon rots away and does not interfere at all with the development of the grass. This plan gives a much more certain effect than the usual method of re-sowing bare places on a lawn.—S. LEONARD BASTIN.

BOOK REVIEW

THE value of "The Pruning of Trees and Shrubs," by W. Dallimore (8vo, illustrated, Dulau, 1926), will be recognised by all who are interested in the cultivation and care of trees and shrubs. Written by Mr. Dallimore, of Kew Gardens, who has had much practical experience of his subject, as well as a theoretical knowledge underlying the practice of pruning, the information it contains is both interesting and instructive.

To those who wish to secure good examples of trees and shrubs in their gardens and grounds, a perusal of the methods recommended for pruning their specimens will be of great assistance. Evidence of neglect and bad pruning of the occupants of parks and gardens are only too common, which a study of the advice given in this little book would prevent. The writer treats his subject in a masterly manner, with instructions for the treatment of a juvenile tree, to its development into an adult well balanced specimen.

The best methods of protecting the wounds caused by the pruning of large branches, from the attacks of fungus and insects are given, and illustrations showing the effects of neglect of these precautions are figured. Many valuable hints are also given in regard to the preservation of old and decaying trees, which from historic or sentimental reasons it is necessary to take steps to preserve. A chapter is devoted to the treatment of broad-leaved evergreen trees, and conifers, while the so-called flowering trees so essential for the decoration of gardens receive attention. Here the reader will find instructions as to the best seasons for pruning, as well as the growths that may with advantage be removed. This applies also to the chapter on hedges, of both the evergreen and deciduous types. To the owners of gardens of smaller dimensions the pages devoted to the pruning of shrubs will be of especial value. Here are indicated the differences in the time of pruning the branches from shrubs which bloom on the wood formed in the current year, in distinction to those plants which bloom on the wood formed during the year previous. An alphabetical list of nearly thirty pages is devoted to climbers and other shrubby plants grown against walls, and many useful directions for the successful culture of these desirable plants are given. The whole book is written in a simple and concise manner, which is readily understandable by the amateur or professional.

R. L. HARROW.

Means of Access to the R.H.S. Gardens, Wisley.—Wisley, as most people know, lies a few yards off the Portsmouth Road on the banks of the Wey, about a mile and a half on the London side of Ripley and about midway between two lines of the Southern Railway from Waterloo. Four stations, two on the Waterloo-Salisbury line, *viz.*, Byfleet and Weybridge, and two on the "new" Guildford line (served by electric trains), *viz.*, Effingham and Horsley, are each about four or five miles from the entrance to the Gardens. The London General Omnibus Co. runs an hourly service of motor 'buses (No. 115), between Kingston and Guildford and this passes within five minutes of the Garden entrance and recently another service of motor 'buses has been started between Horsley and Ripley village. Passengers by the latter service can alight at Stratford Bridge, half a mile from the Gardens.

The Gardens are open to those bearing Fellows Tickets (each of which will admit three), between 9 a.m. and 7 p.m. on weekdays. The Sunday opening does not start until May 2nd, and continues during the summer from 2 p.m. to 6 p.m.

The ATCO MOTOR MOWER

Gone are the Bad Old Days

Gone are the bad old days of slow and inefficient turf culture—this is the ATCO era—these are the days of better lawns, maintained without heavy labour and with a minimum of expense. The ATCO is used by over eleven thousand Turf Culturists because it is the most efficient Motor Mower extant.

Prices from 30 Guineas

THE COOL CULTURE OF CINERARIAS.

THE antipathy which seems to be inherent in the minds of many towards the culture of cinerarias because of their being an easy prey to green fly has not entirely disappeared. It was bred and fostered in the days when only the large-flowering sorts were known, but when the light, graceful star forms were introduced and found so many admirers quite a number of gardeners began to adopt a more conciliatory attitude to a plant that hitherto they had looked upon more in the light of an enemy. To-day we have progressed far in understanding the culture of these greatly improved and admittedly beautiful greenhouse flowering plants. While our forefathers perpetuated their stock from offshoots or suckers and, consequently, always had them on hand, we have no occasion to do so, as the highly finished strains leave nothing to be desired. We recognise them as indoor annuals, quick in growth, succulent and therefore when in full vigour needing sufficient water at the right time. We know them as being best served when cultivated in an atmosphere in which great heat on the one hand and cold on the other is avoided. In a nutshell, cinerarias dislike extremes of temperature, and those who would avoid pitfalls will endeavour to strike the happy medium, and grow their plants under cool conditions without excitement. As is known, it is usual to sow seed in the warmth of the greenhouse in June for flowering in March following, and early in April if plants are wanted to bloom by December. Mellow loam and leaf-mould with the addition of a little sand passed through a sieve and rendered fine is the ideal compost in which to start the seed. As soon as the seedlings are well into their second leaf, then is the time for their first shift into small pots. In removing them into final pots a small proportion of old manure can be added to the compost suggested. During their early stages it is better to err on the side of coolness than subject plants to a close, stuffy atmosphere.

I find that in transferring them to their summer quarters a cold frame in a north aspect is best, and the pots should be stood on a bed of fine ashes clear of each other so that the foliage, which adds considerably to the beauty of the blossoms, is not liable to become broken or bruised. My experience prompts me to say that plants so located and treated, having the lights off whenever possible, are in prime condition by the autumn, when they can be taken indoors and given a place not far removed from the roof, where they can obtain light and air. Occasional supplies of soot water keep them vigorous and healthy. One of the secrets of producing cinerarias with fine heads of bloom is a long period of growth under cool conditions, and it is when the reverse of this treatment is given that trouble with green fly invariably commences.—W. F.

NICOTINE INSECTICIDES.

THE nicotine, derived from tobacco, is the gardener's friend, used judiciously, his enemy used indiscriminately. Our manufacturers have devoted much time and care to the perfecting of the various compounds—pure nicotine and materials containing it—so that the gardener, who may be suffering loss through some pest to his crops, may be able to eradicate that pest in a simple way, if he follows faithfully the directions accompanying each bottle or packet, as the case may be. Even in recent years there has been a great advance in the preparations of various kinds and forms. Of course, we all know that nicotine is poisonous and must be used with great care. Some of us know how offensive it is in an old favourite pipe, sometimes, when it has not been duly cleaned. Possibly it was a pipe of this kind that I once found a carnation enthusiast using in his glass structure in a northern town. The greeting was quickly over, as I preferred the manufactured nicotine compounds to that from my friend's pipe. He said he was killing green fly on the plants. The pipe and its contents were strong enough to kill the user. That was one primitive way of applying a nicotine remedy. The general way is to apply the remedy in vaporising or fumigating, when the contents of the house are quite dry, but I have always found it advisable lightly to damp the path; furthermore, the vapour or the smoke is more efficacious when the weather is calm and rain drizzle has almost hermetically sealed the tiny openings between the squares of glass. The smoke remains dense in the structure for a considerable time. If the weather is windy and the ventilators are not very close-fitting, many injurious insect pests will recover from their sudden fainting fit and soon go on again with their destructive work. The vaporising of plants should be done in a similar way, and, in both instances, the remedy is more complete if applied on two consecutive nights not over strong, than on one night quite at full strength. In solution form, whether applied by sponge or syringe, the best time to use it is in the evening and to moisten thoroughly all parts of the affected leaves, stems, etc. The foliage will be dry, or almost dry, the following morning and in every instance, after fumigating or syringing, the ventilators at the top of the house should be opened a little before the sun shines strongly on the house.

Manufacturers and vendors supply at reasonable prices nicotine fumigators and vaporising fumigators which will last in good condition for many years if taken care of. It is better to use such than to make a guess at it with make-shift appliances. Some, again, do not require any vessel, I refer to those applied in dry form; shred, cone or sheet. Practically all the leading manufacturers and vendors supply, with the insecticides, tables showing their strength and how to ascertain the cubic feet of various glass structures. I have had practical experience of Messrs. Richard's "XL All" compounds, Darlington's Patent "Auto-shreds," McDougall's Fumers and Sheets, Abol Insecticides, Corry's, Bentley Limited, Cross and Sons Compounds, Osman and Co.'s, W. Wood and Sons, Hunter and Gow's Nicoticides, and several others, and have found them all very efficacious. These insecticides may be obtained by readers from firms and nurserymen advertising in this journal.—HAMPSHIRE.

THE HARDINESS OF GEUMS.

I WONDER what the general experience is in regard to the culture and staying power of geums? Since the advent of that well known variety Mrs. Bradshaw and, more recent still, that of Lady Stratheden with rich golden yellow flowers, they have become extremely popular. Personally, I cannot bring myself to regard geums as hardy perennials—though classed as such—in the same way as one looks upon, say, pyrethrums or campanulas, inasmuch as geums, after being planted out a couple of years or so have a way of damping off, if one may describe it as such. A bed, comprising two dozen plants—two years old—which I saw in March, had all perished, the leaves having all gone mouldy and the roots had died. My own experience with them prompts me to say that, to keep up a stock of Mrs. Bradshaw, one should sow seed every year, and not trouble further with plants after their second season of blooming. In a flower so prolific it seems to be the one weak point, *i.e.*, it has little or no staying power; but my experience may not coincide with that of other readers who grow it in the south of England.—W. LINDERS LEA.

PREPARING THE GROUND AND PLANTING BORDER CARNATIONS.

MOST cultivators, I think, prefer to plant young carnations as early in September as possible, and to have the ground well prepared some weeks in advance of the planting period. Even if one gets well rooted layers set out in October, there is every chance of the plants doing well—especially when we get mild and open weather such as we experienced in November and December, 1924. Throughout those two months there was little or no frost and the temperature even as late as December 20th reached 53 degrees F. It may be worth while stating that our rooted layers were set out late in October of that year, and the plants flowered exceptionally well in 1925.

Those, however, who may have wintered poorly rooted layers in cold frames or have left the layers attached to the old plants in the open, should make a start now, and have these young plants set out in their flowering quarters.

We find that plants grow well and flower splendidly on a border having a western aspect and sheltered from the east and north. The soil is deeply dug and manured and, just before planting, old lime or wood ashes is spread over the surface soil. The September set out plants are looking very healthy at present, although a few had been partly raised from the soil in the early part of the year, owing to the frosts and thaws acting on the earth. It sometimes happens that one wants to get up a stock of some variety, or special coloured favourite, but finds when layering that many good shoots, or growths, on the earmarked plants are far too short for layering. Well, what is to be done? The answer is, pull off carefully those fine healthy shoots, then dibble them into sandy soil in a cold frame and keep them close—and shaded from bright sunshine—for a few weeks. We did this with shoots of a floriferous red variety called Mrs. Wilson, and had nicely rooted plants in less than seven weeks time from date of inserting the shoots, and out of forty-two shoots put in, only one failed to root.—DAVID ARMSTRONG.

WATER LILIES IN CONCRETE PONDS

GORGEOUS water lilies can easily be grown in small artificial ponds made of concrete or some similar substance. All that is required is a quantity of good garden loam and preferably some kind of receptacle to hold it together under the water; a little manure may be added to the loam with great advantage, but only if a flow of water is provided; otherwise, an offensive smell and scum are apt to prove troublesome.

In a small tank the loam may be spread over the bottom; in a large tank it is better to place it in heaps where the lilies are desired, and in some kind of receptacle. The receptacle may be an old basket, a tub, or merely a circle of stones or turf; it should be about 18ins. to 24ins. in diameter.

Plant out in April or May. The best method is to empty the tank or pond and to plant the lilies in the soil at the bottom. Shallow planting is desirable, the soil being some 6ins. to 9ins. deep and the roots buried in that to a depth of 3ins.

When the pond cannot be emptied the planting is more difficult. The usual plan is to plant the lilies in some receptacle first, then to sink them in the water. Or, if the soil is already there, to plant the lilies firmly in small baskets, in cardboard boxes or even in a brown-paper parcel full of loam—anything which will allow the roots to pass through or will decay quickly. These are then slowly dropped into the pond and planted as firmly as possible in the soil at the bottom, stones being laid on either side to hold them in place.

There should be 18ins. to 24ins. of water above the plants; they will easily reach the surface and flower in season.

Beginners should take care that they really obtain choice varieties, for, the pond being small in their case, greater satisfaction is obtained from quality. The double white must be included; if another white is desired, then Marliacea albida may be grown. Ellisiana, vermilion; odorata sulphurea grandiflora, yellow; Marliacea rosea, red; Laydekeri fulgens, amaranth; Aurora, orange red; Caroliniana perfecta, salmon pink; Arc-en-ciel, salmon red; William Falconer, red;

SALE OF ROSES

At 33⅓ per cent. less than catalogue prices.

HAVING so far sold our stock of Roses that the catalogue is no longer a reliable source of selection and not having enough each of different kinds to justify advertising the balance in named collections, we are offering what remains of our stock of bush, standard and climbing Roses in carriage paid quantities in varieties of our selection, at **33⅓%** less than list prices.

The varieties are all first-class (not an obsolete one among them), the trees are excellent and, while all buyers will get remarkably good value for money the first comers will have the advantage of newer and more expensive varieties for as long as stocks last.

KNAP HILL NURSERY
WOKING STATION, SURREY

and a white and a yellow pygmæa would make a fine dozen, easily picked up in any nursery supplying aquatics, all well tested, old, but good varieties.—CLYDESDALE.

TRADE NOTE

All gardeners will welcome the new preparation of Messrs. Vinolia Company, Limited, known as "Sprinko." It is a toilet soap compound, and will be found excellent for cleaning the hands after a few hours' work in the garden. Motorists and mechanics will also find it of great service. One of its good points is that it is equally effective in hard, soft, pond or salt water. The majority of us when working in the garden generally find some little difficulty in removing dirt and grease from the skin, and this preparation undoubtedly does what it claims to do. It is obtainable in two sizes, and Messrs. Vinolia state that they are willing to send a free sample to any of our readers who care to apply to "Sprinko," P.O. Box 52, Blackfriars, London, E.C.4.

PUBLICATIONS RECEIVED.

"The Sweet Pea Annual for 1926." published by the National Sweet Pea Society, price 5s. A volume which all lovers of the sweet pea should procure if they are not already members of this promising Society. It indicates to some extent the increasing interest which is being taken in sweet pea culture throughout the country. The secretary, Mr. A. C. Bartlett, is to be congratulated on the excellence of the publication and for his activity on behalf of the Society, which shows a substantial increase in membership year by year.

"Plants from Seed," by A. J. Macself. Published by Messrs. Thornton, Butterworth, price 6s. net. Another member of the Home Garden Book Series which all amateurs will find of the greatest interest and assistance in their gardening duties. It is written in an easy style and in simple language which will be readily understood by all. There are a number of excellent half-tone illustrations and colour reproductions throughout the pages, which add considerably to the attractiveness of the book.

CATALOGUES RECEIVED.

Miss Stanistreet, Killaloe, Co. Clare. Spring list of violets containing a unique collection.

Messrs. The Barnham Nurseries, Limited, Barnham, Sussex. List of ornamental shrubs with numerous illustrations.

Mr. George G. Whitelegg, The Nurseries, Chislehurst, Kent. A general list covering a wide field, including alpine and herbaceous plants, trees and shrubs, and roses.

Messrs. Messenger and Co., Limited, Loughborough. The new edition of this catalogue of horticultural buildings is an excellent publication in every sense of the word. It contains one of the most comprehensive series of illustrations in line and half-tone of greenhouses, conservatories, porches, summer-houses, etc., which we have seen. In addition, at the opening of the brochure, many practical hints and technical advice are given on the construction and equipment of glasshouses generally as an aid to success in the cultivation of plants, fruit and flowers under glass. It is a handsome brochure, and we have pleasure in bringing it to the notice of our readers. A copy may be had on application to Messrs. Messenger.

WE much regret an error which appeared in Mr. J. Lionel Richardson's advertisement on page v. in our issue of April 3rd, 1926. The varieties which received First Class Certificates should have read as follows: Narcissus Glorious and Beersheba.

"I *trap* the sunshine!"

"That's why all these plants of mine are so big and sturdy. They've had all the sunshine they needed—and more—because they've been under the Chase Continuous Cloche all along. It lets in all the warmth of the sun and traps it—there's none wasted, because there are no shadows to keep any out, for the Chase Continuous Cloche consists entirely of glass and wire. Much better than a frame with wooden sides and framework to block out the light—cheaper too. You can put a whole garden under glass this way at very little expense. I tried just a dozen "A" Cloches to begin with—now I'm using over two hundred regularly."

The Chase Continuous Cloche is freely ventilated and need not be removed for watering. It gives complete protection from birds, animals, cold, and excessive rain, and prevents the surface of the ground from caking.

For general use, order "A" PATTERN, 7 ins. high; box of 12 enough for 14ft., 18/-; 24, 35/-; 52, 65/-. For fairly large plants, "B" PATTERN, 9in. high; set of 15, enough for 22½ft., 35/-, 50, 60/-.

Write or full particulars.

Whitworth Works, 31, Tilton Road, BIRMINGHAM.

A Prolific Garden

cannot be maintained without the aid of some kind of manure. Stable manure is now scarce, and is bulky to cart and spread on the land. No artificial will altogether take the place of natural manure, but a good well-balanced fertiliser, used during the growing season, is a wonderful aid in producing high-class garden crops. No fertiliser is cleaner, more effective, or economical than

PEARSON'S CHEMICAL MANURE

which is compounded from the purest chemicals. It contains every element necessary to plant life which is not present in any ordinary garden soil. A glance at the analysis will prove that this manure is as cheap as any on the market, while nothing can beat it in ease of application and results.

ANALYSIS

PEARSON'S "CHEMICAL MANURE"
(ARTIFICIALLY COMPOUNDED)

Contains at least 11·79 *Phosphates, soluble and insoluble;* 6·68 *Potash;* 6·44 *Nitrogen* (*Ammonia Nitrogen* 4·56, *Nitric* 1·88).

Per cwt. 25/-, ½ cwt. 13/- carr. paid. ¼ cwt. 7/-, 14 lb. 4/6, 7 lb. 2/9, carr. forward.

NEW HARDY CRIMSON BROOM

AT Chelsea Show (1925) *the King said, "That red Broom is certainly very striking." This was the new crimson Broom "Dorothy Walpole," which received the unanimous Award of Merit from the R.H.S. as well as other distinctions in London and on the Continent.*

In the "Field," a well known ex-Curator of Kew Gardens wrote: "The richest coloured Broom known is one named 'Dorothy Walpole.' It is as hardy as the common Broom . . . and is very free-flowering . . . the colour is rich velvety crimson . . . more attractive than any of the coloured Brooms yet seen." The colour far surpasses Cytisus Dallimorei, and the growth is as vigorous as C. Andreanus; it requires no special treatment nor any kind of protection whatever—just a hardy shrub for ordinary garden soil in any part of the British Isles, however far north.

A Vice-Chairman, Floral Committee, R.H.S., wrote: "Everyone who has seen my plant has been astonished at its warm glowing red," and from a lady in Devon: "I am so delighted with the Broom 'Dorothy Walpole.' It has done splendidly and is like a sparkling gem in the garden—one mass of flower."

Strong pot-grown plants now ready for planting out, to flower in May, 12/6 each. Carriage paid rates to any station in Great Britain or Ireland: One plant, carriage paid, 15/-; two plants, carriage paid, 28/6; three plants, carriage paid, 41/-; six plants, carriage paid, 79/6. Coloured illustration sent on application if THE GARDEN *is mentioned.*

ON CODDLING PLANTS

A FORTNIGHT ago an article appeared in THE GARDEN in which Flora Dysart mentions a few capricious plants. Our contributor was polite about them, so polite and so kind that I suspect she must have an angelic temper. Do plants appreciate the fact that gardeners with a sweet disposition say nice things about them, however crotchety they may be, and that all blame for failure lies at the door of the gardener and is not owing to the sneaky underhand temperament of the plant? I doubt it. We are given detailed instructions about growing a number of difficult plants; we become frightened of them. They appear such tyrannical beings; we give in to all their whims. As like as not they do not appreciate this loving care and, like certain savages, decline to live, and so we are left with unbecoming brown skeletons that have cost us money.

There is another method of treating capricious plants, an entirely opposite treatment, that I have tried and in many cases have found successful: that is, to ignore them. Before approaching the plant, think out the approximate place where *you* would like to see it. Provided that a marsh plant is not placed in a dry wall or a woodland plant in full sun in a dry border, pay little attention to what is told you. Then approach the plant with a bold face, tread on it and kick it, clutch it in one hand and a trowel in the other, and shove it in, if possible while talking hard to some friend, who hates plants, about the League of Nations or the price of bacon. I learnt this invaluable lesson in the first instance with Gentiana sino-ornata, which is supposed to be difficult and is not. Mr. Clarence Elliott and others give detailed instructions about peat and how to use it, which, I think, are unnecessary. At any rate, I laid my best plant of this incomparable gentian on the top of some nobbly loam between two stones, was called away, and promptly forgot all about it. It was never planted at all; but it is still my best plant. It has had numerous bits hacked off it, and it is still about a foot square. This curious treatment, at the first instance, obviously startled it, so it started off to show what it could do. I was so surprised with my success that I have tried the same off-hand manner of planting, though not quite so negligently, with other plants, such as Shortia uniflora and Incarvillea grandiflora, with equally gratifying results.

In fact, I am sure that a number of capricious plants only laugh at you, if you mother them and take an immensity of pains over their comfort. Flora Dysart mentions Aquilegia glandulosa as a difficult plant, and I agree. Unfortunately, nurserymen consider that they should be planted out as tiny morsels, and I have not the heart to tread on such an innocent-looking shrimp of a plant. If some kind nurseryman would present me with a big clump, it would give me great pleasure to kick it around the garden and then plant it. I am sure it would succeed.

Many gardeners are, I think, inclined to keep plants far too long a time under their personal supervision. The consequence is that they are handled too frequently, which is often injurious to them. Many of the primulas object strongly to pot treatment, and so do many natives, such as Dryas octopetala, which certainly responds better to coarse treatment than to coddling. There is a great deal to be said in favour of early planting, however small the plants may be, in preference to the old method of letting them get established in pots. The more they get in the way of mothering the more stimulus and artificial conditions they require; whereas if they are left to themselves, they respond quicker to their environment in a natural manner. Deaths may be more, though I doubt this; but the survivors are usually stronger and more healthy as the result of finding their own feet than if their way is made smooth for them. Horticulture has risen to a science, but science and common sense should run hand in hand, and common sense says that the more a plant is grown in as natural a manner as possible the healthier it will be. This applies equally to alpines, shrubs, herbaceous plants and bedding plants. Numbers of so-called failures in various areas are undoubtedly due to an undue regard to their health, that and a lack of knowledge of the broad lines of their requirements.

E. H. M. C.

OWING to the extraordinarily early season, the schedule of the first Show of the Rhododendron Society, to be held on April 27th at the Royal Horticultural Society's Hall, Vincent Square, has had to be considerably enlarged. It is to be hoped that all readers who are interested in this marvellous flowering shrub will make an effort to make this Show a success. Schedules and entry forms may be obtained from the Secretary of the R.H.S.

AMONG THE ARTICLES IN OUR NEXT ISSUE WILL BE:

THE ORANGE CORNER IN THE GARDEN, by Edward Cahen.
SOME UNCOMMON PEAT PLANTS, by A. T. Johnson.
AQUATICS FOR PRESENT PLANTING, by T. W. Briscoe.

Digitized by Google

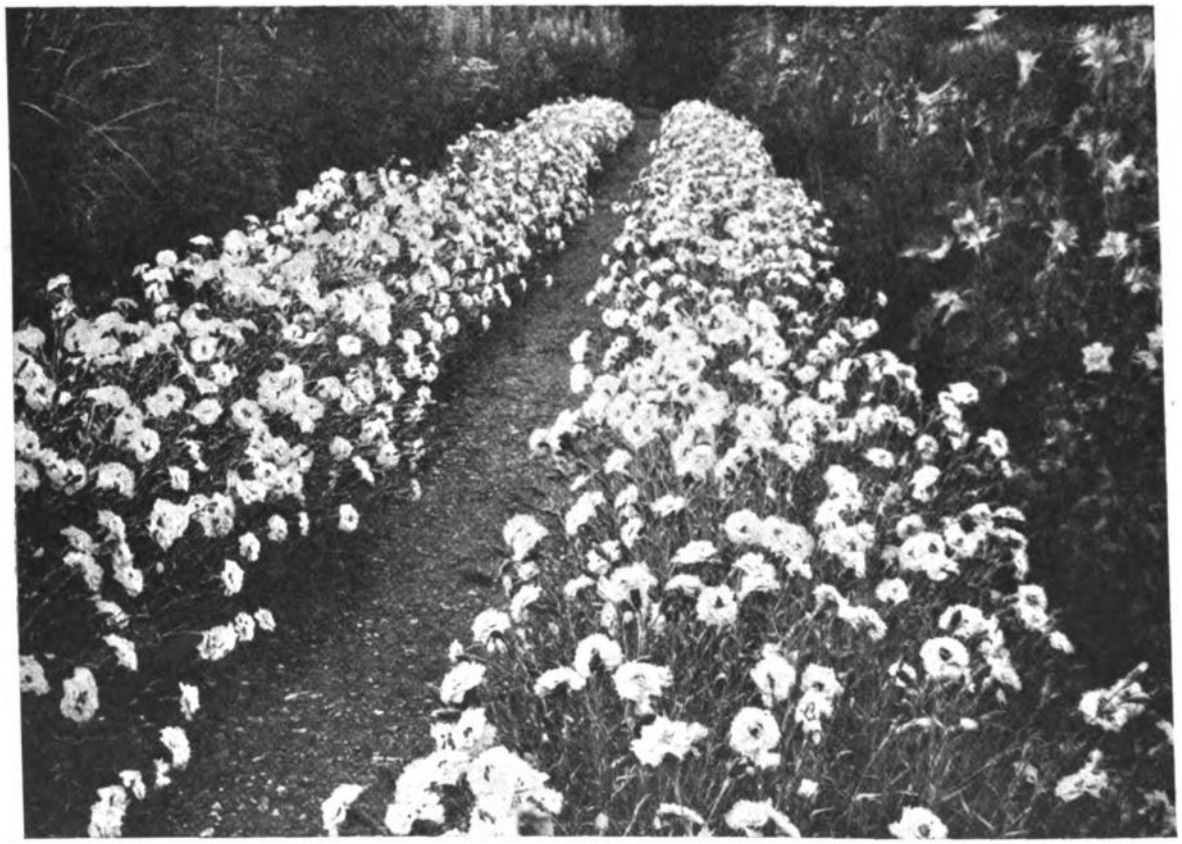
EDGINGS FOR HERBACEOUS BORDERS

A FORMAL edging to a herbaceous border is not an absolute necessity provided the plants in the front row do not exceed 18ins. or so in height and are brought well forward; still, an edging gives a pleasant finishing touch to the whole and undoubtedly makes for neatness. To begin with "dead" edgings, which have the advantage certainly of preventing the border soil getting on to path or lawn, they may be of tiles, slate, wood, bricks or stone. Of these, tiles are the ugliest, more particularly those dreadful varieties that have a sort of cable pattern or are scalloped at the top, while slabs of slate are uninteresting and slightly funereal, if durable and tidy-looking. Wood was a favourite edging material in the formal gardens of the past. John Rea in his "Flora" gives preference to it over box and sets forth at length the manner of preparing, painting and fixing what he calls the "rails," which were to be 5ins. broad, 1½ins. thick and nailed on "legs" 18ins. long for driving into the earth. Bricks were also much used for this special purpose in old gardens, and these Loudon and Wise in "The Retir'd Gardener"—really a free translation of "Le Jardinier Solitaire"—advise should be set on edge and the ends cemented together. The bricks were to be very well burnt and when in position should stand about 2ins. clear of the ground.

Of stone edgings there are three varieties. The first consists of rectangular blocks of stone roughly dressed and set flat; the second of well weathered rockery stones standing at least from 10ins. to 12ins. above the level of the path; and the third consists of a narrow strip of "crazy" paving. By far the most satisfactory of these is number two, as over the high stones can be grown an infinite variety of trailing and creeping plants, such as dwarf campanulas, aubrietias, alpine pinks, phloxes, veronicas, violas, helianthemums and saxifrages which, if selected with care, will provide a blaze of colour from May to September. The least satisfactory of the stone edging is the "crazy" type, but this can be quite tolerable if well laid and the crevices between the stones filled with suitable plants of low growth and neat habit.

As a "live" edging dwarf box (Buxus suffruticosa) comes easily first, although its leisurely growth is apt to be a trial to impatient gardeners, and Euonymus japonicus, especially in its gold and silver varieties, is satisfactory in mild districts, but in cold ones is liable to get badly cut by frost if hard clipped. Ivy edgings, once very popular for both beds and borders, are now rarely seen, but if well kept they are not unattractive, although they share with those of box the drawback of harbouring snails. Bush ivy may be used for the purpose, but the small-leaved clinging kinds—the Irish variety grows fastest—the trails of which are pegged down as they grow, is better. Vinca minor may be treated in the same way. V. major is too straggling to be satisfactory. Some of the thymes, notably T. aureus and T. argenteus, are suitable, and in the late Canon Ellacombe's wonderful garden at Bitton, Erica carnea was used as an edging, but beautiful as this is when in full bloom it has rather a dull appearance when out of flower.

Among herbaceous plants appropriate for such a position Nepeta Mussini is one of the most pleasing. The soft lavender of its cloud of delicate blossoms seems to harmonise with almost all other colours, and it remains in bloom throughout the whole summer. It is hardy nearly everywhere. Still, in an exposed situation it is advisable to let the old flowering-stems remain as a protector during the winter. Old plants of nepeta do not stand moving well, but cuttings strike easily. The best of the perennial candytufts for an "edger" is the dwarf and free-flowering Iberis correæfolia, said to be a hybrid between I. sempervirens and I. saxatilis. It is not to be trusted to come true from seed and should be propagated by cuttings. White pinks, especially the old small-flowered very fragrant kind, now unfortunately scarce; Veronica incana with its silver leaves and blue flowers; violas, both the ordinary bedding varieties and the species gracilis and cornuta; and the dwarf campanulas, in particular pusilla, are all recommendable; but for a shady border there is nothing to surpass our humble old friend Saxifraga umbrosa, better known by its vernacular names of London pride, St. Patrick's cabbage and—quaintest of all—Kiss-me-at-the-garden-gate. S. u. Ogilviana is the best variety to use. Asperula odorata also will thrive in practically sunless conditions, and its little white flowers are effective in a mass if insignificant individually.



A FINE EDGING OF A MODERN HYBRID PINK.

Digitized by Google

Thrift makes a nice green cushiony edging in sun or semi-shade, but the rather aggressive pink of its flowers does not always go well with the general colour-scheme of the border and the white blossomed sort is less satisfactory in habit. The colour of A. maritima Laucheana is deeper and more agreeable in tone than the ordinary type. Two plants which are not as often employed for border edgings as they deserve to be are Tiarella cordifolia (the foam flower) and Thalictrum adiantifolium, both of which prefer a moist soil to a dry one. The feathery white blossoms of the tiarella are beautiful, but the little flowers of the thalictrum are quite uninteresting and are better removed, for its charm is to be found in its finely cut bright green foliage, which so strongly resembles the fronds of the maidenhair fern. For a very dry situation there is something to be said in favour of Waldsteinia trifolia, the barren strawberry. Its flowers are not attractive and are often only sparsely produced, but if its rather pertinacious runners are pinched off it forms a band of deep green foliage.

R. E. HEAD.

SUGGESTIONS FOR SUMMER BEDDING

ALTHOUGH the unlimited use of beds in gardens is no longer practised, nevertheless there are times and places when bedding is both necessary and fitting. In these cases, beds should be grouped, either in a small garden or on a lawn where they are seen from windows, as single beds are uninteresting from any point of view. They should be simple in shape, and, if on a lawn, they should have a good margin of grass round them; narrow grass margins are finnicking in appearance and difficult to keep in order. When deciding on the flowers to be used in beds, certain considerations must be borne in mind: (1) Flowers with a fairly long period of blooming must be chosen; (2) they must be effective in the mass—the individual beauty of the flowers is not of first importance; (3) they must look well from every point of view, as beds, unlike borders, have to bear scrutiny from all points of the compass. Having made up our minds to accept these limitations, the next thing is to decide upon a colour scheme. This is important, as the formal nature of bedding makes the colours used conspicuous, and badly chosen varieties cannot be inoffensively obliterated by the judicious addition of other plants as they can in a mixed border. Nor is the bedding alone the chief factor in a colour scheme. The general *ensemble* of the garden must be thought of and sympathetically treated. The size of the garden, the plan of it, the nature of the boundaries, the immediate background of the beds, and, above all, the prevailing "feeling" of the garden, must all have a place in the final decision. Formal gardens must have formal and restrained bedding; charming old-world gardens can be given riotous beds of mixed colours; a little secluded garden may have a restful scheme of greys and mauves. Americans are making "ghost gardens"; dim, cool places planted with silvery grey and white; but these are not practicable unless the whole area of garden is large enough to contain a small specialised garden. Then, of course, there are beds which are bedded out, say twice a year, with spring and then with summer bedding plants; and beds in which perennial plants or small shrubs are permanently planted. But these latter belong to herbaceous gardening and, for the purposes of this article, only those beds which have their flower contents changed every year will be dealt with.

GROW PELARGONIUM PAUL CRAMPEL BOLDLY IN A BED BY ITSELF.

To keep beds well filled and interesting is neither easy nor cheap, but the effects which can be produced with care and a certain expenditure compensate for these drawbacks. Summer bedding plants should be cleared by the beginning of October, when the beds are ready for digging and manuring; autumn bedding is lifted about the end of May.

Of summer bedding there is no end. The following are a few schemes:

(1) Tobacco plant—either pink or white—with a good carpeting of alonsoa. This is a delightful combination for beds near house windows, as the evening scent of the nicotiana is delicious.

(2) The well known dahlia, Coltness Gem, has proved good for summer bedding. It is dwarf, very bushy and rich scarlet in colour. It has a remarkably long flowering period, and begins to flower in early July. No carpeting or edging is needed, as the plants themselves fill any space adequately.

(3) Standard or bush heliotrope grown with a carpeting of pink cupid's sweet peas is pleasant in a quiet way.

(4) Coreopsis with Nemesia cœrulea makes a dainty yellow and blue effect; while white campanulas carpeted with Viscaria cœrulea have been tried with good results.

A STRIKING BED OF SCARLET GLADIOLI AND GOLDEN VIOLAS.

Digitized by Google

(5) Mauve pentstemons with a sprinkled undergrowth of matthiola or any other grey-leaved bedding plant, together with purple pansies, makes a restful scheme. Grey undergrowth is also very effective as a foil to vivid bedding plants, such as cannas, some of the geraniums, Salvia splendens, and other similar subjects.

(6) Beds of mixed African marigolds in orange, middle yellow and pale yellow shades are gay and inspiring. They also possess the advantage of a long season.

(7) Tall white antirrhinums planted with pale, cool pink gladioli are charming. Another bolder effect can be gained by planting scarlet gladioli with golden violas.

(8) Cosmeas are not grown enough in this country. They are quite delightful in beds if a tall effect is wanted. Well grown plants should be used and planted, say, 8ins. apart to give a good display. The foliage is feathery and is apt to look thin unless enough plants are used. Shades of blush pink, mauve and white can be used together.

(9) A great deal has been said of late years against scarlet geraniums, as we call the zonal pelargoniums; but, given the right setting, these much abused flowers are handsome and good. They should be used to lighten a sombre or heavy garden where delicate effects would be overlooked. Use either the old-fashioned Paul Crampel or a soft red such as Mrs. Bartleman, and, if grown near spikes of the tropical-looking yucca, the result will be most striking. But grow them alone and grow them boldly. Do not repent half-way and introduce some other plant to soften the effect.

(10) Salvias can be used for the same purpose. Salvia splendens is vivid and has a long flowering season. With a background of heavy yew it looks particularly fine. This, again, should be used alone or with a heavy grey foliage plant. It is of shrubby habit and does not look well when mixed with tender annuals. Salvia patens is blue and more delicate, so that it can be used with great effect with pink or white stocks, or with a carpeting of white or purple violas. D. JOAD.

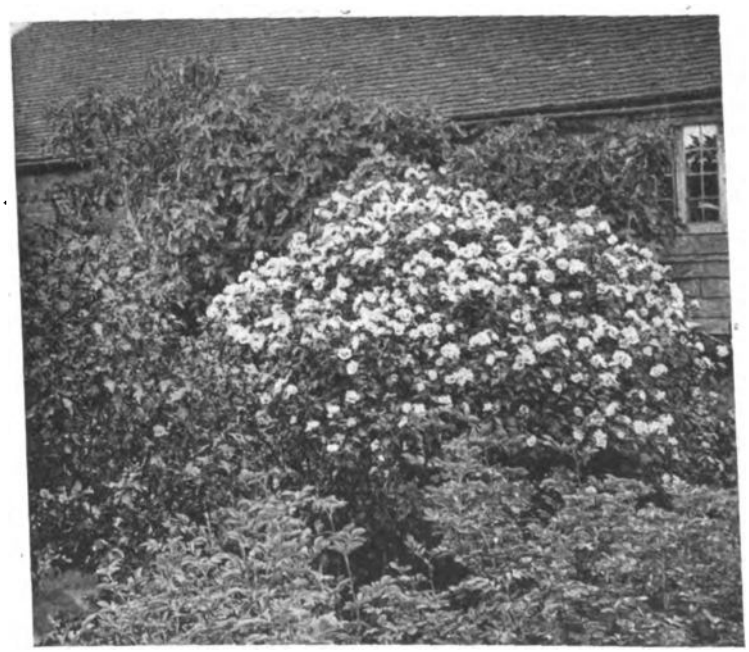
SHRUBS FOR WALLS

BY W. J. BEAN.

(*Continued from page* 218.)

THE shrub FENDLERA RUPICOLA is not often seen, but it is worth growing on a south wall for its abundant, faintly blush-tinted white flowers borne in May and June on long slender shoots of the previous year. Judging by some flowering shoots from Mr. Bowles which I saw a few years ago, it must succeed very well at Myddleton House. It has small leaves, and each flower is an inch or rather more wide, with four petals and yellow anthers. It is hardy in the open, but seems to need the heat of a wall to bring out its greatest beauty. South-western United States.

FREMONTIA CALIFORNICA.—Although this Californian small tree is very nearly hardy in the London district, for it has succeeded well in a sheltered nook against the Temperate House at Kew during a good many years, it is worth a place on a south wall because the greater heat there induces it to bloom more freely. It need not be trained close back to the wall like a fruit tree, but allowed rather to form a bushy growth coming away from the wall 1ft. or 2ft. It flowers during summer, and its waxen, rich yellow blossoms, each 2ins. to 3ins. wide, are remarkably distinct and beautiful. There are two forms in cultivation, one with slightly overlapping lobes, the other with narrower ones. Both are handsome, but I think the former preferable, especially as the flowers are larger.



HIBISCUS SYRIACUS AS A WALL SHRUB.

GARRYA ELLIPTICA.—Although quite hardy in the south of England—and even in the Botanic Garden at Cambridge, where it has grown to be an enormous shrub—this likes a wall in the less sunny north. It also flowers rather earlier there. Its long, silvery grey, tail-like catkins, produced in winter and early spring, make it at that season a very pleasant evergreen. California.

HIBISCUS SYRIACUS is another shrub perfectly hardy in the south, but in the north giving much better results on a south wall than in the open. In dull, cold autumns, even in the south, its flowers, which open normally in September, will often fail to develop properly. I remember, many years ago at Belvoir, that a large plant growing against one of the terrace walls of the castle used to give a fine display of blossom.

HOLBŒLLIA.—Two species are grown on walls, *viz.*, H. latifolia from the Himalaya, and H. coriacea, introduced by Wilson from China, both evergreen. The former is the more tender, although it does well at Nymans in Sussex. Both are genuine climbers, and on walls have a tendency to form a tangle at the top. Their natural habit, I suppose, is to climb over trees. The flowers, which are unisexual, are dull white or purplish, the most notable feature of the plants being the fruits, which are sausage-shaped and purple.

HYDRANGEA PETIOLARIS.—This hardy Japanese climber deserves to be grown more frequently. It is deciduous and clings of itself to walls, which it will cover as completely as ivy does. Of course, it is leafless in winter, but, on the other hand, produces in June broad clusters of white flowers. It is well worth trying for a north wall.

ITEA ILICIFOLIA.—This evergreen shrub is not found to be hardy at Kew, but it makes a charming furnishing for a wall, both on account of its dark shining green, rather holly-like, leaves and its slender, pendulous racemes, 6ins. to 12ins. long but only ¼in. wide, densely set with small greenish white flowers in August. Western China.

JASMINUM.—No wall of any considerable length can afford to be without the beautiful winter-flowering J. nudiflorum, whose bright yellow, abundant flowers, opening as the weather permits between November and February, make it the gayest of wall shrubs at that season. It flowers quite well on a north wall, although not so freely as on those where it gets direct sunshine. The common jasmine, J. officinale, charming for the fragrance and beauty of its white flowers from June onwards, can scarcely be left out either. Being a true climber, it will make a thick tangle towards the top of a wall or house front.

LINDERA PRÆCOX.—One of the aromatically scented shrubs that belong to the bay laurel family, may be mentioned as a March-flowering plant which does best on a wall, where, if given a sunny position, it blossoms so freely as to be very pretty. The flowers are small, yellow tinged with green, and produced in numerous small clusters. Japan and Korea.

Digitized by Google

LIPPIA CITRIODORA, the well known "lemon-scented verbena," most people will like to grow for the charming fragrance of its leaves; but near London and northwards it will need wall protection.

LONICERA.—The common honeysuckles, L. Periclymenum and L. Caprifolium, in my experience, find an ordinary wall too sunny for them and they become infested with aphis there. They are better as one sees them in nature, with their roots in the cool shade of a bush or hedge, their flowering parts only reaching the full sun. In the moister parts of the country, however, they are often charming on a wall facing nearly north. L. tragophylla, which also fails in full sun, I never saw so fine as with Mr. Eley at East Bergholt in Suffolk, where he had planted it on the north side of a wall and over the top of which it had formed a tangle of its long, slender shoots and was a beautiful object in July. The finest of the honeysuckles in regard to its blossom, it has, unfortunately, no fragrance. The two winter-flowering species, L. fragrantissima and L. Standishii, are, neither of them, in any way showy, but they are often grown on walls for their sweetly scented flowers which continue to open through the winter when the weather is favourable; they are, however, usually at their best in February. More out-of-the-way species are: L. Giraldii, with very hairy shoots and leaves, and curious purplish red flowers covered with yellowish down; L. alseuosmoides, with purple and yellow flowers: and L. Delavayi, with pale yellow flowers. All these are evergreen and prefer a west or north-west wall. For the warmer, moister parts of Britain, L. etrusca and L. italica may be recommended, both being singularly beautiful honeysuckles from the south of Europe and vigorous deciduous climbers.

MAGNOLIA GRANDIFLORA is, of course, very well known as a wall tree—it is more than a shrub; but, although slow-growing, it is quite hardy in the open near London. On a house front it always appears to me ungainly and unsuitable, but it flowers much more freely there, and its individual blossom is about the finest we can see in the open air in Britain. It will cover the front of a good-sized house, and keeping it pruned and in order, with the necessary tying-in of young shoots, entails considerable labour. Another evergreen species, M. Delavayi, can only be successfully grown against a wall, except in such places as Cornwall, where it makes a particularly striking tree. It has the same defect as M. grandiflora, in that the size of its leaves and the thickness and strength of its shoots make it somewhat unsuited for wall cultivation. Its dull green leaves are often 12ins. long and half as wide, and its dull white flowers 7ins. or 8ins. across.

MYRTUS.—We may grow at least four kinds of myrtle on walls, where they are only injured by the severest winters. On the south wall, the common myrtle (M. communis) will blossom quite freely. Without the same associations, but even more attractive on a wall, is its variety tarentina, the Tarentum myrtle; this has much smaller leaves and flowers, but the latter are often very abundant. The other two myrtles are of Chilean origin, M. Ugni and M. apiculata, both often given the generic name of Eugenia. They have the typical myrtle flowers and bear many palatable blackish fruits.

(*To be continued.*)

THE GREY BULB-ROT OF TULIPS

THE grey bulb-rot of tulips is a well known disease in many of the bulb-raising districts of Holland, where it causes very serious damage to the young bulbs in the nurseries. The disease has very rarely been reported in this country, but recently there are indications that diseased bulbs are being imported from Holland. Therefore it is important that the disease should be recognised by all growers of bulbs on a large scale and measures taken to stamp it out before it obtains a footing in this country.

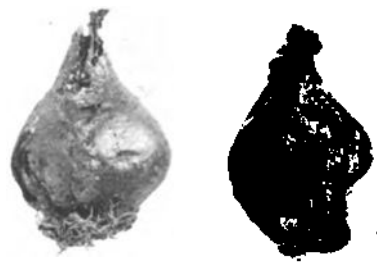
DISEASED BULBS.
Showing young sclerotia developing on the shoots.

Grey bulb-rot is caused by a fungus Rhizoctonia Tuliparum, which does not possess reproductive spores, but spreads by means of fungal threads growing out from the affected bulbs. The fungus winters in the soil in the form of small, dark-brown bodies termed sclerotia, which consist of fungal threads very compactly woven together. Only the outer layer of the sclerotium is dark brown in colour, and if one of the sclerotia be cut in two it will be seen that the interior is light yellow. The dark brown and light yellow colorations are very characteristic and aid in distinguishing Rhizoctonia Tuliparum from other fungal diseases which may infect the tulip bulb.

The first evidences of the disease in the Dutch bulb nursery are the presence of bare spots in the tulip beds in the spring, where the plants have failed to come up. These bad spots, or "kwaden plekken" as the Dutch term them, are very heavily infected with the fungus. Nearly all the bulbs planted in such an area are usually so severely injured that they fail to grow. When infected bulbs do produce leaves, the growth is much retarded and the whole shoot soon withers down, due to the fact that the fungus has rotted off the lower portion just at the neck of the bulb.

When diseased bulbs are dug up and examined it is found that they are more or less rotted, the infection beginning at the tip of the bulb and working downwards. A rather striking feature is that the soil adheres very firmly to the rotted portions, due to the presence of a felt-like covering of fungal threads which binds the particles of soil to the bud scale. The infected bud scales show a distinct change in appearance; the diseased tissue of the scale becomes more or less translucent and greyish in colour, in marked distinction to the healthy tissue, which is quite opaque and white. The greyish appearance of the diseased tissue is very distinctive of this disease, and has led the American investigator Whetzel to name it the grey bulb-rot. As the lower portion of the bulb is the last to be attacked, an abundance of healthy roots is usually produced. The dark brown sclerotia of the fungus are found in the soil surrounding the diseased bulb and also very typically on the neck of the bulb.

The measures taken to combat this disease in the Dutch bulb nursery are largely preventive. It has been found that the disease spreads very slowly through the soil from one bulb to the next in the tulip bed, therefore the Dutch growers make use of a special tool termed a "Tulpenstecker" to remove any diseased bulbs. The tulpenstecker is a metal cylinder, with a pair of handles at one end, which is pressed down over the diseased bulb, and bulb and soil contained within it are carefully removed and burned. No practicable method of sterilising bulbs or soil has been evolved, though Whetzel states that on a small scale the use of commercial formalin (at the rate of 2lb. to one square yard diluted with enough water thoroughly to wet down through from 6ins. to 8ins. of loosely spaded

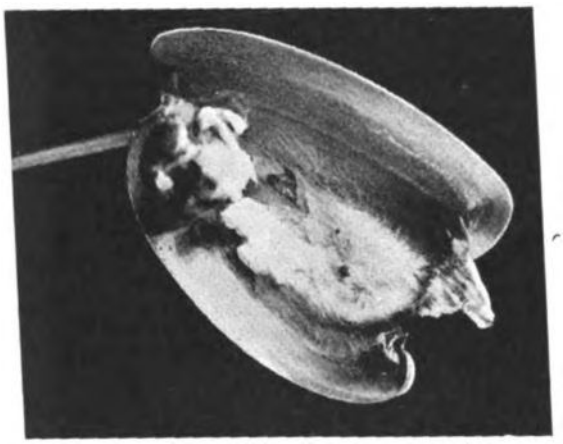


DISEASED BULBS.
Showing mature sclerotia at the neck of the bulb.

Digitized by Google

soil) is very efficient. He has also successfully tried pan steaming the soil for one hour.

It is extremely difficult to detect the presence of the fungus on bulbs in the dormant condition which have been imported into this country from Holland to grow on for flower. It is only after the bulbs have been placed under suitable conditions of warmth and moisture, such as are present in the forcing house, that the fungus develops. When growth of the bulb takes place and the young shoot appears it is seen that it is covered with a greyish white felt of fungal hyphæ. In many cases the leaves fail to unfold and the shoot soon rots off. When the leaves do develop they are stunted and malformed, due to the fact that their apices have been attacked by the fungus. The upper surface of each leaf usually becomes covered with a white felt of fungal hyphæ, which is densest in any depression such as that formed at the midrib. The characteristic sclerotia of Rhizoctonia Tuliparum very rapidly develop on the fungal felt on stem and leaf. At first they are white in colour, but later they acquire the typical dark brown colour of the mature sclerotium.



MALFORMED TULIP LEAF.
Showing white felt of fungal threads.

A forcing house containing many boxes of infected tulips is a very striking sight, which brings home forcibly to the observer that the presence of the fungus is responsible for a considerable amount of loss to the grower. In one nursery from which the disease has been reported it is the custom to plant the bulbs fifty in a box. In many of the boxes containing infected tulips only two or three plants developed leaves, and one with as many as twenty-five healthy bulbs was rarely obtained. At this nursery every precaution was taken to ensure that soil and boxes used in growing the bulbs should be free from infection. It is certain, therefore, that the disease was imported on the bulbs, which came from Holland. It is interesting to note that the tulips were obtained from three growers, two of whom had their nurseries in the same district and were responsible for sending badly diseased bulbs, while the third had his nursery in another district and sent perfectly healthy bulbs. This indicates that the British nurseryman would do well to be very careful with regard to the source of his tulips, and he should buy from the Dutch grower who is able to produce a clean bill of health for his nursery. If the disease has been observed among his tulips, the grower will be wise to reject boxes and soil for further use, and he should dispose of them very carefully so that there is no risk of infecting fresh boxes and soil.

The Botrytis blight of tulips, a disease caused by the fungus Botrytis tulipæ, has often been confused with grey bulb-rot. This disease is more common in this country, and is spread much more rapidly, because reproductive spores are formed, as well as sclerotia. The tulip is usually attacked much later, often when it is in flower, and every part of the plant may be affected. The sclerotia formed are smaller than those of Rhizoctonia Tuliparum, and have a black external coat with a white interior. They are generally scattered all over the outer bulb scales and not confined to the neck of the bulb as in Rhizoctonia Tuliparum. The fungus causes light brown withered spots to appear on leaves and flower petals, and the small black scelerotia often occur in the centre of these discoloured areas. This disease is also imported on Dutch bulbs, so that it is an additional reason for selecting with great care the grower from whom the bulbs are purchased.

DISEASED TULIP SHOOTS.

E. J. CADMAN.

DWARF CONIFERS FOR THE ROCK GARDEN

THE great increase that has taken place during late years in the number of rock gardens has created a considerable demand for dwarf, evergreen trees and shrubs. Such plants are extremely useful in rockeries, for not only do they introduce an air of reality to the surroundings of alpine plants by representing the stunted character of trees at alpine altitudes, but they relieve the winter bareness and, later on, form ideal backgrounds for choice flowering plants. Probably the most popular plants for this purpose are the dwarf conifers. These were brought into very prominent notice in 1923, by the publication of "Dwarf and Slow Growing Conifers," a book by Mr. Murray Hornibrook. Unfortunately, however, it is not possible to procure some of the plants there mentioned and others can only be obtained with great difficulty. Mr. Hornibrook explains in the preface to his book what great trouble he had in obtaining plants true to name. Some have never been common; some

A ROUNDED HUMMOCK OF PICEA EXCELSA GLOBOSA NANA.

come and go; some of the original plants have been lost; new forms constantly appear and they often masquerade under old names, or maybe under a variety of names. Consider the many varieties of the common spruce (Picea excelsa). Some of them have been known since the middle of last century, but whether the original stocks exist in all cases is doubtful. In 1900 a very considerable number of abnormal seedling spruces of the common European kind, were raised in the Forest Garden at Adlisberg, Switzerland, which exhibited all kinds of variations from the type. The seed was collected from a single tree, an abnormal tree of erect habit with a peculiar bunching character of the branches. The seedlings when seen by the writer were thirteen years old and 16 per cent. were of normal habit, with single trunks; 31 per cent. had developed several trunks from a common rootstock, while 53 per cent. had formed dense, round cushion-like plants of heights varying from a few inches to several feet. At that time it

Digitized by Google

appeared to be possible to match many of the cultivated, named varieties among these seedlings, yet, with age, differences may have arisen. This indicates how difficult it may be to keep dwarf conifers true to type, for one kind being out of stock, it may easily be substituted by another which may alter in character as it advances in age. However, there are certain well marked kinds that are in general cultivation and those mentioned below are offered for sale at moderate prices in nurserymen's catalogues.

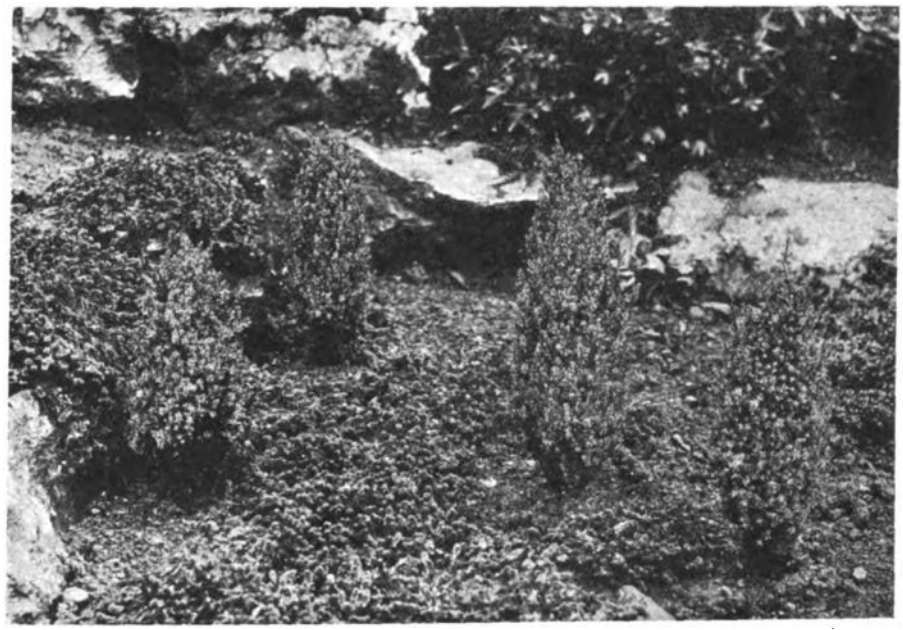
CUPRESSUS OBTUSA, one of the most important cypresses from the Far East, has long been cultivated by the Japanese, both as a timber tree and for garden purposes. It is one of the most popular trees for dwarfing in Japan and in the hands of Japanese gardeners it has developed a large number of varieties of very striking character. In most instances the branches of these varieties are stunted and they bear a dense mass of short branchlets covered with bright green or golden foliage. They are among the best of the dwarf conifers suitable for rockeries and the following varieties are easily obtainable. C. obtusa var. compacta, a dense bush that, with age, reached 2ft. to 3ft. high and as far through; varieties nana and pygmæa, which are similar to the last named, but smaller in stature; nana aurea, a small dense plant with golden foliage; and tetragona minima, a variety with a looser branch system than other varieties and a curiously angled system of branching. Most of the varieties of C. obtusa are characterised by the dense, flat, fern-like appearance of the branches and leaves and they sometimes appear in nurserymen's catalogues under the generic name of chamæcyparis. Quite distinct from other varieties is C. obtusa var. Sanderi, a dense, slow-growing plant, often not more than 9ins. to 15ins. high, that only produces the juvenile type of foliage. The leaves are about one-sixth of an inch long and they stand well out from the shoot. Their grey green colour makes them very attractive. This variety is sometimes catalogued as Retinispora Sanderi and Juniperus Sanderi.

CUPRESSUS PISIFERA, sometimes called Retisispora pisifera, produces a number of varieties in which the juvenile type of foliage persists for many years. Most of these varieties are extremely beautiful, particularly those with gold, sulphur or silver-coloured foliage, but most of them grow too large for the rock garden. The varieties nana aurea, a dense rounded bush with golden foliage, and ericoides, a greyish-green leaved plant, are worth consideration where space is restricted.

CUPRESSUS LAWSONIANA is another species that is prolific in varieties. Most of them are too tall or too spreading for the rock garden, but there are several dwarf kinds that are easily obtained. Two good green-leaved varieties are compacta and pygmæa, both dwarf, compact plants with normal foliage, that take many years in attaining a height of 2ft. Two charming varieties with the juvenile type of foliage persisting are Fletcheri, which forms a slow-growing pyramid of plumose habit with blue-green leaves; and Rheingold, a bushy variety with pretty golden foliage. Both make good rock garden plants. Another dwarf variety is Fosteriana, a slow-growing, compact variety with blue-green leaves, that never grows tall. There is some doubt as to whether the variety now on the market is the one originally described under that name. Cupressus thyoides var. leptoclada is a dense bush, bearing a mixture of the mature and juvenile types of leaves.

Among the junipers are several species that are naturally small in stature and others that are dwarf forms of taller-growing species. On hillsides Juniperus communis is often found less than a foot high and sometimes as a prostrate shrub, but given good soil and suitable position it may reach a height of 10ft. or 12ft. However, there are forms that never grow big and the neatest of them is J. communis var. compressa. This forms a tiny pyramidal tree with a close, formal branch system of erect slender branchlets, clothed with glaucous green leaves. It grows very slowly and takes many years in attaining the height of 2ft., although it may grow twice as high in the end. The name of J. hibernica compressa is sometimes applied to the plant. The variety alpina is a more or less prostrate shrub and the variety canadensis is a spreading bush often not more than 12ins. high. J. horizontalis is a spreading species that may be planted on banks where a low covering is required. J. squamata is another dwarf species, suitable for the rock garden, but at present it is rather expensive. J. Sabina and its several varieties are all suitable for covering banks where tall plants would be out of place. As a rule they do not exceed 3ft. or 4ft. in height, especially where the soil is on the poor side. The variety known as "Knap Hill," is one of the most effective.

Pinus montana var. Pumilio is one of the dwarfest of the numerous forms of the mountain pine. It can be planted with effect in the rockery. Another dwarf pine is P. pumila, a small, dense bush from Siberia.



A GROUP OF JUNIPERUS HIBERNICA COMPRESSA.

There are many dwarf forms of the common spruce (Picea excelsa), some of the best of the cushion-like forms are dumosa, pygmæa and Gregoriana. Both Thuya occidentalis and T. orientalis provide dwarf varieties. Of the former, globosa, Little Gem and pygmæa are all low-growing bushes, suitable for restricted places, while of T. orientalis the varieties compacta and ericoides should have attention. The last named variety is peculiar in retaining the juvenile type of foliage. W. DALLIMORE.

SERVICE FOR READERS

Though so many subjects are dealt with in each issue of THE GARDEN, it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our new Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, whether advice is sought as to—

RESTOCKING A GARDEN, COLOUR SCHEMES FOR GARDENS, THE BEST PLANTS FOR CERTAIN SITUATIONS, WHERE TO OBTAIN NEW AND RARE PLANTS, INSECT PESTS, NAMING OF PLANTS, AND THE HUNDRED AND ONE OTHER DETAILS RELATING TO THE GARDEN—

there is always information available from a staff of expert contributors and consultants; *and there is no charge for this.* It is one of the additional means of Service which THE GARDEN is glad to render to its readers.

All communications should be addressed to the Service Department, THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C.2.

NOTES OF THE WEEK

A DECORATIVE EVERGREEN SHRUB.

THE genus arctostaphylos belongs to the heath family (ericaceæ) and is represented in cultivation by some ten or a dozen species in varieties varying in habit from trailing plants useful for carpeting to shrubs and small trees; nearly all are evergreen. The genus is widely distributed in the Northern Hemisphere, ranging from California to the mountains of central Europe and Britain, and northern Asia; while one variety is found in China. In cultivation all require a moist well drained peaty soil and a sunny position. They do not transplant readily, and it is better to grow them in pots until they are of sufficient size to be transferred to their permanent positions. Two species are found wild in Britain. Of these, Arctostaphylos Uva-ursi (red bearberry) is the more common. This is found in the higher mountains of the north of England and Scotland, and also in central Europe and California. The British form is more stunted in habit than the Californian, and plants usually offered by nurserymen are of American origin. Several forms are sent out under trade names, but they vary little from the type. Planted in a suitable position in a peaty border or rock garden, Arctostaphylos Uva-ursi makes a good evergreen carpet and spreads rapidly, producing its clusters of small, attractive, pink, heath-like flowers at the ends of its branches from April to June. Cuttings will root readily and afford the best means of increase.

Arctostaphylos alpina is the other British native. This is much rarer, being confined to the higher Scottish mountains, where it is found growing in association with another rare alpine ericaceous shrub, Loiseleuria procumbens.

It is of dwarf creeping habit with short racemes of white flowers followed by black edible fruits. Of no outstanding garden value, this shrub is nevertheless interesting to the collector of novelties. In the autumn its leaves turn a bright red. It requires cool, moist conditions in cultivation, and may be propagated by division, seeds and cuttings.

The Californian species provide us with the best-flowering members of the genus, and the outstanding one is Arctostaphylos Manzanita—commonly called Manzanita in its native habitat, where it grows into a small tree about 20ft. high. Although introduced about thirty years ago to Britain, it has never become widely grown, and it is difficult to understand why such a splendid winter-flowering evergreen has been so little appreciated. In cultivation it forms a medium-sized evergreen bush with thick leathery leaves like a eucalyptus, borne in such a way that only the edges of the leaves are presented to the full light of the sun. There would appear to be several forms in cultivation, which show slight variation in season of flowering, colour of flower and bark of the young shoots. How these forms originated it is difficult to say.

The flowers are borne in terminal racemes, and vary in colour from white tinged with pink, to pink; but I have never seen one with so much colour as that figured in the *Botanical Magazine*, Tab. 8128.

By selecting the different forms it is possible to get a continuous display of flowers from December to April. The earliest form I have seen is growing in a sheltered, sunny border in the Royal Botanic Garden, Edinburgh, where, regardless of weather conditions (for the flowers are not damaged by frost), it flowers freely throughout the winter.

ARCTOSTAPHYLOS MANZANITA, A FINE EVERGREEN SHRUB FROM CALIFORNIA.

Several good specimen plants are growing at Kew. These vary in the colour of their flowers and bark, but none commences flowering until March. The bark varies from green to red, and it is noticeable that the green stems are thinner than the red, although bushes with the former are the more free-flowering. On the older branches the bark peels off after the manner of an arbutus.

For a considerable time it was generally supposed that cuttings of Arctostaphylos Manzanita would not root. This idea, however, is erroneous, as numerous young plants have been propagated by means of rooted cuttings at the Royal Botanic Garden, Edinburgh. Cuttings made about 3ins. long of the tips of the branches root readily in about three months, if inserted in pure sand. They can be taken at almost any time. It is unwise to remove any more than about two leaves at the base of the cuttings, and these should then be inserted at a depth sufficient to keep them upright. Care should be taken in potting them up. I have obtained excellent results from batches put in in December. Fruits are rarely produced on cultivated plants, and imported seeds prove difficult to germinate. Some authorities recommend subjecting the seeds to heat before sowing, and any trouble taken in raising this plant is more than repaid by the sight of a bush in full flower.

Another Californian species worth cultivating is the rare Arctostaphylos tomentosa, a white-flowered form distinguished from all the others through being densely clothed with stiff hairs.

Several other species and varieties are grown, but there is little to merit their inclusion in other than a botanical collection.—F. P. K.

PLANTS FOR DAMP SOILS.

IN many gardens there are low-lying parts where only moisture-loving plants will thrive. Such places are not made as beautiful as they should be; instead of rushes and marsh weeds being allowed to flourish in them a selection of water and bog plants should be planted. It may be that some cleaning-out work will be necessary first—the removal of rushes and similar plants. All such work should be very thorough, as very small roots will grow and form big masses of stems and leaves if they are left in the ground. Where there is a basin containing muddy loam full of weeds, the most satisfactory way of dealing with it is to excavate the whole of the soil as well as the weeds and their roots, and partly to replace with good clean loam; this will soon become muddy and a fit rooting medium for aquatic and bog plants. The sloping sides of such hollows must be dry-cleaned, as it were: poor soil taken out and good put in where the new subjects are to be planted. It is much easier, afterwards, for the cultivator to keep the whole of the surroundings in a clean condition. The following kinds of plants are suitable for growing where their roots will be constantly in water: Alisma (water plantain), Juncus communis, menyanthes, nymphæas in variety, parnassia, Peltandra virginica, Ranunculus lingua, stratiotes and Typha latifolia. On the slopes and near the margin of the water, plant spiræas, Acorus Calamus, Caltha palustris, Bottonia palustris, and the pickerel weed in masses at the edge of the pond, and clumps of bamboos.—G. G.

SOME MODERN ERIGERONS, OR FLEABANES.

WE have in cultivation quite a number of good erigeron species, many of which are of high beauty, and there are some growers who affect to despise the modern forms, generally hybrids, of the majority of which the parentage has not been disclosed. Most of these are exceedingly beautiful, however,

Digitized by Google

and those who desire to have in their gardens the best of the modern plants of the day cannot afford to neglect these very charming flowers. They all partake of the general features of the erigeron species—aster-like flowers with narrow, graceful ray florets. They form excellent border flowers and prefer a good, well manured soil in sun or partial shade and not too dry below, yet not what may be called moist, either. Propagation is effected by division.

A very pretty hybrid which grows to about 2ft. in height is that called Antwerpia, which has large and charming flowers of a fine shade of lavender blue. This is a great favourite with many. Asa Gray, which has been for a good many years in cultivation, and in which it is not difficult to trace the influence of E. auriantiacus, one of its parents, has flowers of a kind of apricot hue. It is very different from all the others and is about a foot high, or rather more.

Elsie is a most distinct little flower, with a dwarf and bushy habit, which will suggest its inclusion in the rock garden or the front of the border. It is only about 6ins. high, and has nice, rosy pink blooms. Edina is esteemed by a goodly number of growers. It is about 18ins. in height and has large white flowers. B. Ladhams is coming greatly into favour and is becoming popular, not only for its appearance in the garden, but also for yielding cut flowers of considerable beauty. It grows about 2ft. high, and gives a plentiful supply of bright rose blooms. Merstham Glory, which originated—or was, at least sent out—by Mr. W. Wells, is very distinct, inasmuch as its flowers open double and only show an eye when they are passing their best. These blooms are violet-blue and are borne plentifully on a plant of good branching habit. Pink Pearl is a comparative novelty. It is another which grows about 2ft. high, but its flowers are of a lovely shade of pink. Its claim to be the best of its colour has much to support it. Although there are others, I shall conclude at present by mentioning the favourite Quakeress, also about 2ft. high, which supplies us with a wealth of bonny flowers of a soft lavender blue, almost reminiscent of the Quaker garb so much worn by the ladies of this faith in former times.

These erigerons are all worthy of the consideration of lovers of the best hardy border flowers, and their extended cultivation is much to be recommended.—S. ARNOTT.

ONE OF THE BEST OF THE FLEABANES, ERIGERON QUAKERESS.

HERBACEOUS PHLOXES & LUPINS: LATE PLANTING.

ALTHOUGH the season is far advanced this year, and the recent warm weather has hastened on growth, it is still possible to plant herbaceous perennials in a number of districts; but the work should be carried out without delay, and particular care should be taken of the plants during the early summer. It must be remembered that these plants will not have made enough root growth before the summer to enable them to withstand a prolonged period of drought, but if the ground is kept well hoed round about them and they are given copious supplies of water in very dry weather, they should not suffer in any way.

Both herbaceous phloxes and lupins are first-rate border plants which have been improved within recent years to a marked degree. The colour ranges in each case are infinitely wider, and their form and constitution have also been greatly improved. These two perennials are inexpensive to buy, will last for many years, succeed in practically any soil—provided it is well prepared—and they need but little cultural attention. Phloxes are particularly adaptable. Their value in the herbaceous border is known to all, but their decorative value in beds alone, and in narrow borders backed by tall evergreen hedges, is not always fully appreciated. In whatever position phloxes are planted it is not advisable to mix the varieties. One colour by itself is far more effective.

A WELL GROWN PERENNIAL PHLOX.

Phloxes have a long season of blooming. The first flowers appear during July, and the flowering carries on until well into the autumn. There is considerable difference in the height of the different varieties; some, such as Thor, will attain a height of 4ft., while others, such as Flora Hornung, do not often grow taller than 1½ft. Phloxes prefer a deeply dug, fairly moist loam which has been enriched with well decayed manure. In the spring they greatly benefit by a light mulching of rotted manure, as they exhaust the soil in which they are growing, and in hot weather an occasional thorough soaking with water is helpful. About 18ins. apart is a suitable distance for planting.

There are innumerable varieties in white, shades of pink, rose, salmon, scarlet, purple and many intermediate shades. A few of the finest white and salmon varieties are: Lady Grisel, an early-flowering white; Europa, another white with a conspicuous carmine eye; Lemon Queen, white with a lemon eye; America, salmon pink; Mrs. M. Van Hoboken, a soft pink; Mrs. Oliver, salmon with a white centre; Elizabeth Campbell, another salmon; and Baron van Dedem, a brilliant orange scarlet. The rose and crimson varieties are very attractive, and among them are Africa, Aegir, and Marechal Foch. A careful choice should be made from the blues, lilacs and purples; Le Mahdi is a fine large-flowered lilac; Reichgraf von Hochberg is a brilliant purple blue; Miss Ellen Willmott a pale mauve flushed with crimson; and Offenbach an attractive lilac.

One of the advantages of the phlox is the ease with which it can be propagated, but it is a great mistake to propagate from inferior stock. Strong and healthy stock should be purchased at the outset, and from this one can produce good young plants either by division or by cuttings of well ripened shoots.

There are several types of lupins suitable for the garden, besides a number of species. Each one of these types has a number of varieties, all fine border plants. The most important class is Lupinus polyphyllus. L. arboreus, the tree lupin, is a splendid shrubby perennial; and the third class consists of a number of hybrids raised by crossing L. polyphyllus and L. arboreus.

Lupins are equally suitable for the semi-wild garden or the herbaceous border, and they are admirable for massing at the edge of a woodland; in fact, no garden should be without some of the modern lupins. They are not fastidious as to soil. If lupins have not been grown to any extent in the garden, try some of the new shades, such as Cross Roads and Downer's Delight or Light of Lodden, a beautiful yellow-flowered variety. Downer's Pink Pearl is really charming; Favorite, a light, clear blue; Sunshine, a bright golden yellow; 21st Lancers, a striking variety with orange standards and lavender keels; Happiness, a rich, deep purple; The Bride, a pale yellow shaded rosy pink; and Excelsior, with handsome tall spikes of reddish purple, should also be tried. The hybrid lupins are semi-shrubby in habit, and of this class a few of the best are Beauty of Somerset, Sweet Lavender and Effective. Lupins and phloxes are border plants which are particularly suitable for the amateur, as they are in no way difficult to grow, and yet they give a fine display of bloom for many weeks. M. P.

PRUNING SHRUBS AND TREES

AS regards the proper pruning of a large mixed shrubbery there are many points, all important, to keep in view, consequently the pruning season extends nearly all the year round. Many subjects are pruned to induce them to flower freely, others for production of large foliage, and all for general effect and tidiness; but here let me warn pruners not to pay too much attention to "tidiness," which often means "good shape," etc., more often than not at the expense of the crop of bloom.

What I propose in this short article is just to run through the months of the year and touch on the most important subjects usually dealt with each month.

I will therefore commence with April. This is a great month for pruning such evergreens as rhododendrons, aucubas, laurels, ilex, ligustrum, laurustinus, ivies—in fact almost all evergreens, leaving the more tender varieties till quite the end of the month. Pruning may, especially in the case of rhododendrons, mean simply removing the terminal buds from shoots which are just a little too long, thereby inducing the lateral buds to break early and ensuring the formation of flower buds for the following season. On the other hand, rhododendrons which are already out of hand, and I know there are many such, may be cut back with safety to any desired height; in some cases they may not break too freely, in this case the terminal buds of the one year growths should be removed the following April. Specimen evergreens should never be sheared over, but cut carefully with the knife, thereby retaining the natural growth as much as possible. Generally speaking, deciduous subjects should give way to evergreens, as in most cases these are considered of greater value, and on the other hand most deciduous subjects will bear, and in fact often require, more drastic pruning than evergreens. During April buddleias, amorphas, some hypericums, lavandula, Perovskia atriplicifolia, etc., should be pruned back to almost ground level, exceptions being Buddleias alternifolia and Colvilei. By this treatment plants never get out of hand or exceed their allotted space. As the years pass, a woody trunk or stem will naturally be formed, but its growth will be slow. Other plants for foliage effect which should be similarly treated are ailanthus and paulownia.

During May rhododendrons should continue to receive attention, for many gardeners will not care to sacrifice the flowers, so as soon as they begin to fade the plants may be pruned into shape. The ilex must, during this month, receive attention, cutting out a branch here, pinching out a terminal bud there, so as to ensure perfectly furnished specimens. Early-flowering deciduous shrubs may be pruned as hard as may be desired, such as forsythias, Cornus Mas, ribes, etc., and such evergreens as have finished flowering, including Berberis Darwinii and other early-flowering berberis; but here again comes the rub, to prune away the flowering wood is to lose the effect of the beautiful fruits in early autumn, so care must be used in selecting only the badly placed shoots for removal each year. Tender evergreens, such as drimys, pittosporum, etc., may be pruned into shape; if these plants have not been neglected it often means that pruning simply consists of removing terminal buds, excepting, of course, those of the leaders.

During June there is a quantity of pruning to attend to, a notable group of trees and shrubs being syringas and laburnums, immediately these have finished their flowering they should be attended to, if only to remove the seed pods, which will now be forming at the expense of next year's flowers. Laburnums usually grown as standards can now be cut into shape and syringas certainly should be properly pruned, due regard being paid to the desired shape of the plant. Last year's growth, which has just finished flowering, should be cut back to two pairs of eyes and these, with proper cultivation and feeding, should each give at least two trusses of bloom, *i.e.*, from the upper pair of buds. The end of June is not too late to finish pruning rhododendrons which have now, for the most part, finished flowering. This applies also to azaleas, but at this season it is necessary to use a styptic where cuts are made or bleeding will take place. If no other pruning is needed, it is still necessary to remove the young seed pods which, if left will seriously deplete the following year's show of bloom.

July is a particularly busy month for the pruner, for there are now three groups of important shrubs needing attention: philadelphus, spiræas and deutzias. All three require similar treatment, and if I say they require somewhat the same system of pruning as does the raspberry I shall be understood by all. Pruning should not be so rigorous as with the raspberry, but on the same lines, *i.e.*, remove the old wood, which has flowered and retain the new. A good many of the spiræas and deutzias will stand this method and give excellent results each year, but it is as well not to cut choice subjects too ruthlessly until one gets to know their habits and requirements.

During the latter part of July and on through the first half of August, is an important time among malus, prunus, cherry and pyrus. Many gardeners understand and practise "summer pruning" of fruit trees. This applies with equal force to the above-mentioned ornamental section and, generally speaking, the same treatment, if properly carried out, will induce greater crops of flowers, better shaped trees and, in the case of those which bear ornamental fruits, better and brighter coloured specimens. On through August attention must be paid to the removal of faded bloom and, where not required for propagation, seed pods, the nipping out of the tips of shoots which look like encroaching on their neighbours' space.

During September comes a lull in the pruning world, and the knife should not be used except when found to be absolutely necessary. The chief reason being that growth everywhere is now practically finished and the wood is ripening. To cut away shoots upsets the natural function of the plant: part of an unfinished process is cut away, consequently Nature begins over again, and to do this she has to produce new material, *i.e.*, new growth. This, from a gardener's point of view, is undesirable, as it means soft sappy growth to be nipped by the first touch of frost. Many gardeners will insist upon cutting evergreens in autumn, for tidiness sake. This is quite wrong: be patient and wait till spring

October, November, December, January and February, constitute the hardwood pruning season, which I think is best understood by the majority of gardeners of all classes and little harm can come to hardy deciduous trees and shrubs by their annual thin out and trim up. But those who study the subject and prune at the proper season during the whole year will have their winters' task considerably lightened, as most of the work will have been done as recommended and considerable time gained, which can then be expended on digging, or trenching where necessary, the shrubbery borders.

March is a month which, coming just between winter and genial spring weather, should make the pruner wary. It is far better to wait a little longer before pruning tender subjects, and in this respect there are many sad tales being told of March pruned ilex and blackened shoots in early May, "the proper time to prune."

Paignton. JOHN HILL.

CORRESPONDENCE

RHODODENDRONS IN VARIOUS AREAS.

SIR,—It is stated in the fore note to the tabular list on page 195 that "rhododendrons of the campylocarpum and Souliei types thrive better on the east coast than on the west." This does not accord with our experience on the Scottish west coast, where RR. Souliei, campylocarpum, cyclium, Williamsianum and myrtilloides may be mentioned as species of those sub-series offering no difficulty in cultivation. The table does not include a report from Argyll, and as for Wigtownshire, where my lot is cast, we are accorded a blank against such generous growers as RR. barbatum, Thomsoni, Loderi, præcox, decorum and oreotrephes. R. Fargesii also is accorded a blank, whereas within a bowshot of my writing-table there is a bush with over one hundred trusses open. Let no west coast amateur be discouraged in planting these fine rhododendrons. It is no more than fair to add a note about the species with which I have failed. No amount of care and coddling will induce R. camschaticum to give me a blossom. It flourishes lavishly in the Edinburgh Botanic Garden. RR. camelliæflorum, giganteum, prophantum, facetum, bullatum and Boothii have perished, or nearly so, from last winter's frost. R. grande has never been satisfactory here, probably because our plants are derived from parents growing at

Digitized by Google

a low altitude, and out of five plants of R. sino-grande, one is dead, two are past praying for, while two on higher ground are all that could be desired.—HERBERT MAXWELL, *Monreith*.

FORM IN GLADIOLUS PRIMULINUS HYBRIDS.

SIR,—I am glad that a number of THE GARDEN has been devoted to the gladiolus this year, for the articles in that and the following number were very instructive, and I see that a correspondent has already (page 194) raised the problem touched on by "C. H. A. S." in his article (page 140) as to form in gladioli. Personally, I am in agreement with this writer concerning the value of primulinus hybrids for indoor decoration, and also on the desirability of avoiding those hybrids which approach the large-flowered in shape. Salmon Beauty, of which I believe an illustration was given on the middle page of the Special Number, under the title of "A Primulinus Hybrid," is, perhaps, worth taking as standard for primulinus hybrids, as it combines the gracefulness of the species primulinus with the display of flower of the large-flowered, and as it is also of good substance, a quality which many of these hybrids lack.

But if all primulinus were modelled on these lines we should get a little tired of them, and other types are very useful to provide variety. Daphne, as illustrated, is typical of many varieties which have flowers very loosely arranged on the spike, and in articles a few years ago in THE GARDEN several writers defended this type as being the most desirable. However, the spreading of the flowers demands a larger number of spikes for an effective display, and many of these varieties have thin petals.

The variety L'Innocence—which, by the way, on my light soil comes pure white—has a very novel shape, and I do not know whether to praise or condemn it. It has a tall, stiff stem with closely set flowers, but each individual flower is quite small, extremely neat and dainty, and very fresh-looking. Unfortunately, as in many medio-prims (if I may use the name), a number of these flowers are not of true prim. shape. I fancy L'Innocence would be best as a choice garden variety.—H. J. WARREN, *Leeds*.

GLADIOLI FROM SEED.

SIR,—It is very gratifying to find so many catalogues and horticultural magazines stressing the ease with which this inexpensive and most fascinating method of making a collection of gladioli may be carried out. May I once again emphasise the following facts: Gladiolus seed *germinates freely, grows easily* and *quickly* (flowers can be had in six months). The gladiolus seeds very freely, and artificial fertilisation carried out by hand is simple in the extreme—at least 85 to 90 per cent. or more of such crosses will set seed in a normal season, and the raiser has the additional thrill of knowing just what the seed is, can indulge in pleasant anticipations and, above all, can work with a set purpose in view. If the seed be from good standard varieties the number of really good seedlings is astonishingly high and very few will be bad enough to discard—only the very best should be named. Compare this with the dahlia or daffodil, where only one seedling out of hundreds, or sometimes thousands, is worth retaining! For the benefit of any reader whose climatic conditions are similar to mine, I give briefly my experiences of seed raising. Prior to this year (1925) I always sowed the seed in boxes containing about 9ins. of good soil in warm situation out of doors as soon as seeds were ripe (March to May), according to date of planting the corms from which the seed eventually grew.

Most of the seeds sprouted in from three to six weeks, but appeared to suffer a check during the cold months (June to August—winter here), and only a few flowered at the end of their first year's growth—I think possibly due to this check. As soon as the foliage withered the corms were planted out in the open in prepared beds—the corms varying in size from cormlet size up to 3½ins. diameter—and next season all the larger corms flowered. This year I kept the seed till early spring and planted in the open in a rather warm position, but found, to my surprise, that, although the soil was kept moist, the seeds positively refused to germinate so long as the soil was exposed to the sun, but, as soon as a covering of straw was applied, germinated and grew vigorously. I am hoping some of them will flower in six months, as I know it has been done here under similar conditions.—AUSTRAL, *Geelong, Victoria, Australia*.

A FINE WINTERGREEN.

SIR,—A week or two ago you printed a note on Pyrola rotundifolia. I now send a picture which shows an unusually fine specimen of it which I photographed in the rock garden house of the Botanic Garden at Nymphenburg. It is not easy to grow this species with much success. P. rotundifolia is frequently seen in shady and rather humid positions in deciduous woods, but it is often difficult to move it into the garden. Once established it ought to remain undisturbed for years. It is the showiest species of the genus, with open white flowers appearing in June or July. In North America it is represented by the similar P. americana, which is apparently somewhat easier to cultivate. All wintergreens are stoloniferous, but like a light sandy soil well mixed with peat and leaf-mould. They will not grow in the common garden soil. Some, like P. chlorantha, P. secunda or P. umbellata, want a dry position, while P. rotundifolia, P. americana, to a certain extent also P. media and P. minor, like a humid or almost wet situation. This is the case, too, with the small one-flowered P. uniflora, sometimes called Moneses uniflora, which is found in moist, cool woods. It has white, open flowers with two-horned anthers.—CAMILLO SCHNEIDER.

PYROLA ROTUNDIFOLIA PREFERS A SHADY MOIST POSITION.

A FREE-FLOWERING WATER LILY.

SIR,—I am writing to express my great appreciation of your Spring Number. The illustration of wallflowers is certainly most excellent. I commenced alpine and water gardening about thirty years ago under the guidance of my old friend, the late E. H. Jenkins, and still have copies of your paper containing articles by him, one of which is a great source of satisfaction to me, describing, as it does, my own small rock and water garden. It is certainly larger to-day, but I doubt if I derive more pleasure than I did when first beginning, though I am as keen as ever. Your article on alpines and water plants in the March 27th issue is A 1. You would, in my opinion, do well, when writing of water lilies, to emphasise those which are particularly suited to small sheets of water and tubs. Many years ago I planted a Nymphæa Marliacea carnea in a small pond, large enough to breed carp in, but it overran everything. Among bog plants I would warn enthusiasts against the bog bean, Menyanthes trifoliata, which, though an aquatic, speedily spreads at a most alarming rate and is as much at home in the bog as in the water. Again I express my thanks for your most excellent articles now appearing.—THOS. P. WEBB, *Hampton Hill*.

THE SCENT OF GLADIOLUS TRISTIS.

SIR,—Perhaps the following observation on another plant may have some bearing on the question of the scent or scentlessness of the flowers of the spurge laurel as recorded by Sir Herbert Maxwell in the issue of THE GARDEN, March 27th. For some years I have flowered Gladiolus tristis in a small conservatory for the—to me—delicious fragrance with which it fills the house. On some evenings the odour is very strong; on others, following dull and cloudy days, it is imperceptible; also that it never comes out so long as direct sunlight is on the plants. One sunny afternoon in 1924 a heavy thundercloud came up about five o'clock, and the premature darkening brought out the blossoms' strong perfume, which disappeared, however, when, after the storm, the sun shone on the plants again at 7 p.m., but, of course, returned once more after sundown. —J. WALLACE WALKER, *Lyntwood, Bridge of Allan*.

SPRING FLOWERS AT VINCENT SQUARE

ALTHOUGH a week in advance of the official Narcissus Show, which at one time was thought to be too early for this season, the sudden change to very summery weather has hastened development so rapidly that daffodils and narcissi were the dominant floral feature of the Show.

The best novelties seemed to be in the giant Incomparabilis section, and particularly those which have coloured coronas. Generally, the colour is given by delicate flushings of pink and of apricot, and when, as is the case with the best novelties, this is on a fairly substantial corona set in the centre of a large, rounded, white or primrose yellow perianth, the effect is delightful. This type of flower is also substantial, so that the blooms will withstand the buffetings of winds—the delicate, semi-transparent floral segments are not for general decoration in the garden or the breezy uplands.

In a splendid collection arranged by Messrs. Barr and Sons there were many seedlings of the type mentioned. These are the latest comers and are not yet named; but Mrs. R. O. Backhouse, although strictly a giant Leedsii variety, showed the charming pink-flushed corona perfectly. Fiery Monarch, of true Incomparabilis type, has a most brilliant corona; while John Evelyn is uncommon in its pretty frilled corona. Inez, in the smaller collection of Mr. F. M. Copeland, is another good example of the pink-flushed Incomparabilis narcissus, and he had quite a number of unnamed seedlings.

The large trumpet daffodils always attract immediate attention, and on the present occasion there were many of such great size that they quite dwarfed King Alfred, which only a short time ago was considered to be the daffodil of daffodils. Van Waveren's Giant, Potentate, Tresserve and General Townsend, in a fine exhibit by Messrs. J. R. Pearson and Sons; Canute, shown by the Welsh Bulb Fields Company; Pilgrim Father, Noble Bravo and Wheel of Fortune, in the most attractive group of Messrs. Sutton and Sons, are the names of some of the best of the large trumpet daffodils, mostly of rich yellow colour; while Carmenta, lemon yellow tube, and Tamora, sulphur yellow tube, shown by Mr. J. W. Barr; and Conqueror, primrose tube, shown by R. H. Bath, Limited, were also splendid examples of large trumpet daffodils.

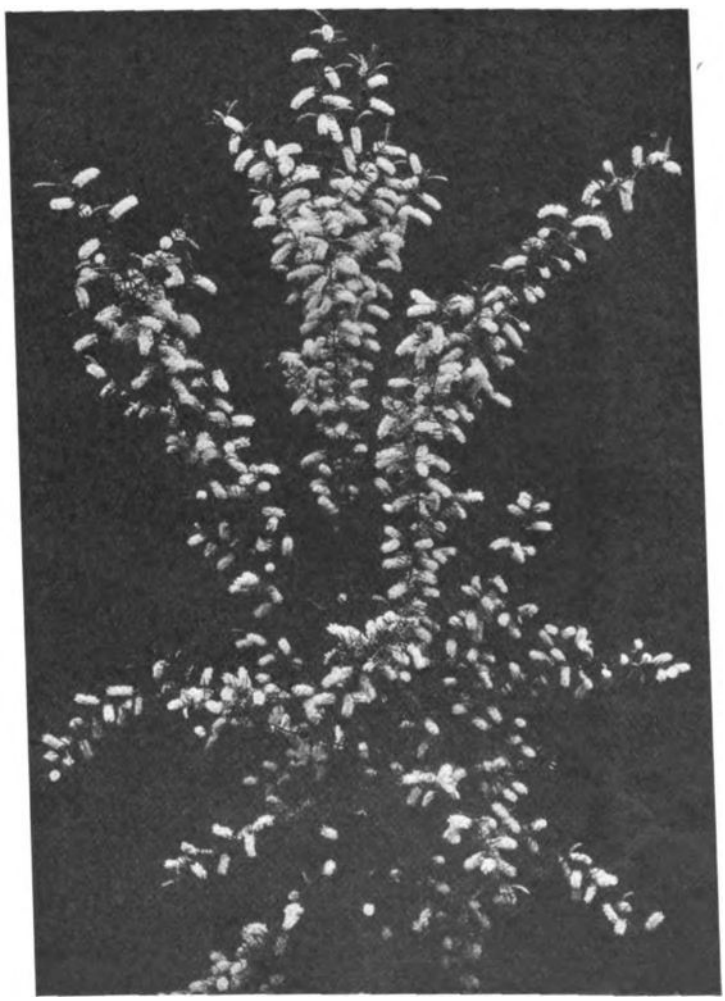
The Barrii type, which has a medium-sized to small brightly coloured corona, was freely shown, and the best varieties included Harpagon, Doctrinaire, Sunset Glow, Owen, Masterpiece, Lucifer, Brilliant Star and Pixie. The best Poetaz varieties combine decorative value with strong, but not too strong, perfume; and of this type a little collection, including Sycamore and Orange Cup, by Messrs. R. H. Bath was admirable.

Of the various uncommon types of narcissi a hybrid Triandrus with a crested corona, shown by Messrs. Sutton and Sons; Milk and Honey, a good double flower; and Snowsprite, one of the very few double Leedsii varieties shown by Messrs. Barr and Sons; Copeland's Triandrus; and the true Jonquil, a most dainty little twin-flowered stem of rich yellow colour and delightful fragrance, shown by Mr. J. W. Barr, are all worthy of much admiration.

While the blooms would not please the florist, who places form in a flower first, and almost last as well, the baskets of the semi-double Tulip Apple Blossom, staged by Messrs. Carter and Co., have considerable decorative value.

What may be the last exhibit of coloured freesias for the year was made by Mr. G. H. Dalrymple. The varieties were much the same as at the previous Show, but they were in such abundance as to make a lovely display. Bluebeard is of blue-mauve colouring; Buttercup well describes the colour, while the flowers are large and rounded; Cream-cheese is of paler yellow and, having long stems, is admirable as a cut flower; Treasure is the largest flower of all and of bright yellow colour lightly shaded with mauve on the outside. Besides the freesias, Mr. Dalrymple brought excellent plants of his Bartley strain of Primula pulverulenta. The different varieties are in pale blush, soft pink and rose pink.

The show auriculas staged by Mr. James Douglas were splendid examples of this fascinating flower. Some of his latest seedlings, especially those of blue colour, seem to be more floriferous than the old, as well as being of new colour. Prince of Tyre, of velvety purple colour; Janet, of rose maroon colour and a yellow zone; and Red Self are excellent varieties.



THE ORNAMENTAL CLUSTERS OF ACACIA VERTICILLATA.

Roses were shown so well that many must have been reminded that it was only about a fortnight to the Spring Show of the National Rose Society. Mr. Hicks had lovely vases of Clovelly, Mme. Abel Chatenay, America and Mrs. H. Stevens. Messrs. B. R. Cant and Sons set up splendid vases of Joan, Lady Wakefield, Golden Ophelia and Mrs. Beatty. Mr. George Prince showed Souvenir de Claudius Pernet, Mabel Morse and Padre, of great excellence, and also had beautiful sprays of the yellow Banksian rose. The cluster-flowered sorts were displayed by Messrs. Frank Cant and Co and by Mr. G. H. Pemberton; the latter had decorative little pot plants of such sorts as Koster's Orleans, Edith Cavell, Echo and Alice Amos; while the former arranged weeping standards of Excelsa and Yvonne above the dwarfer La Reine Elizabeth, Queen Wilhelmina, Orange King and other sorts.

Carnations were staged in considerable quantity and of the accustomed quality by Messrs. Allwood Brothers, Mr. C. Engelmann and Messrs. Stuart Low and Co., who displayed the best varieties. Adjoining their carnations, Messrs. Stuart Low and Co. had an attractive group of well flowered mimosas, chorozemas, the fragrant Boronia megastigma, splendid spikes of hippeastrums and yellow spathes of Richardia Elliotiana.

A restrained and satisfying group of forced shrubs was set up by Messrs. R. and G. Cuthbert, who employed bushy plants of Viburnum Opulus, V. Carlesii, Wistaria sinensis, Laburnum Vossii, Deutzia gracilis and Staphytea pinnata. The clematis plants associated with vines, Azalea Hinodigiri and other shrubs, by Messrs. L. R. Russell, Limited, included President, Mrs. Cholmondeley, Fairy Queen and King Edward VII.

Colonel Stephenson Clarke sent from Cuckfield, Borde Hill, splendid trusses of his rhododendrons. Beauty of Tremough, Barclayi, Duke of Cornwall and arboreum were magnificent. Mr. J. Klinkert grouped topiary specimens; and Mr. J. J. Kettle staged fragrant violets.

Polyanthuses of enviable size and colours were shown by Messrs. Blackmore and Langdon and by Messrs. John and A. H. Crook. The latter had a mixed collection, while the Bath firm grouped their large exhibit in good distinct colours. In Mr. Miller's exhibit we noted the old favourite double lilac primrose and the double white, as well as laced polyanthus and Miller's yellow strain. He had many vases of the deep blue Muscari Heavenly Blue, which was also shown in great quantity by Messrs. R. H. Bath, Limited.

Messrs. F. G. Wood of Ashtead showed some interesting primulas: P. chionantha, a fairly recent arrival from China that has taken kindly to our climate and seems to have come to stay in our gardens, where it should soon be well known, for it is a fine plant, distinct in its colouring of grey-green, black and white, and in its rich fruity scent; P. Wardii, from Tibet, another vigorous plant, whose large starry flowers of the usual primula pink have sometimes a slight twirl to them which gives the flowers an elegantly gay

Digitized by Google

carriage. In the middle of the exhibit was a bank of P. altaica, which replaces our yellow primrose in the Caucasus and eastwards; it is an old garden plant, but its delicate, cool lilac is hardly matched by any of the hybrid primroses, and it is wonderfully free-flowering. Beside it was an older plant still, Prince Silverwings, a double red and white polyanthus nearly lost to cultivation.

Messrs. Cutbush had a patch of the rare little white daffodil Moschatus of Haworth, Tulipa Clusiana (splashed cherry red and white), and the lavender daisy Bellis cœrulescens, between large bushes of rhododendron and azalea. Their Daphne oleoides, with its loose heads of large rose-purple flowers fading to white, was a finer plant than the wild form in southern Europe, and is probably a hybrid between it and D. Cneorum.

Messrs. Reuthe's exhibit contained, as usual, a large number of rare and distinguished plants; Schizocodon soldanelleoides, a sub-alpine woodlander from Japan, looked very hearty and vigorous, carrying three or four soldanella flowers in pale pink veined with crimson on 2in. stems; Anemone Halleri, a version of our native A. Pulsatilla in deep violet, is an excellent garden plant and would associate well with Fritillaria armena, which has the look of a tall, chrome yellow snowdrop.

Messrs. Clarence Elliott showed the rare old red Dusty Miller, whose fragrant, wallflower red flowers go so well with the powdered leaves; Petrocallis pyrenaica and a large pan of Androsace arachnoidea superba.

Messrs. Prichard grouped large patches of Gentiana angulosa (a large, vigorous and comparatively easy form of G. verna); the double white wood anemone, A. nemorosa fl. pl., whose doubling has given a formal charm to its flowers and prolonged their life without robbing them of their grace; and Narcissus Johnsoni or Queen of Spain, that very graceful hybrid of nature's raising.

Messrs. Waterer showed the curious dead white of Trillium grandiflorum against the pale china blue of Mertensia virginica; the double gorse and a vigorous clump of Gentiana verna.

Messrs. W. L. Rogers showed off their alpines in large clumps, the buttercup yellow of Morisia hypogæa against the dark chocolate of the form of Anemone Pulsatilla rather oddly named "rubra," embroidered with the white Hutchinsia alpina.

Messrs. Maxwell and Beale showed good stocky plants of the sub-arctic Phyllodoce empetrifolia; while Messrs. Hemsley's Nurseries showed Mazus repens, a very prostrate creeper with flowers that look like flattened-out lilac snapdragons, and other miniature alpines.

NEW AND RARE PLANTS.

AWARDS OF MERIT.

ACACIA VERTICILLATA.—Two very decorative plants of this mimosa, or, as the Australians term it, wattle, were shown. They were slender and erect and bore plenty of oblong spikes of pale yellow flowers. The narrow sharp-pointed leaves are borne in whorls. Shown by Messrs. Stuart Low and Co.

DRIMYS AROMATICA.—This species, which is a native of Tasmania and South Australia, is not usually considered to be so hardy as the South American Winter's Bark (Drimys Winteri), but the sprays from Sussex had quite a robust appearance. It is a stocky little shrub with red stems and buds and smooth dark green leaves. The little clusters of yellowish flowers were freely produced in the axils of the leaves. Shown by Mr. Gerald Loder.

MAGNOLIA CONSPICUA R. VEITCH'S VAR.—This is a very desirable variety of the well known Yulan tree. The flowers are larger and more rounded than those of the type. Shown by Colonel Stephenson Clarke.

MECONOPSIS BAILEYI.—This is one of the uncommonly beautiful blue poppies from China and the Himalayas. It was quite a charming plant, nearly 2ft. high, furnished with soft pale green leaves and bearing solitary well disposed flowers of sky blue colour. Shown by Lady Aberconway.

RHODODENDRON ADENOPODUM.—A graceful truss of soft pink flowers which have small rosy spots and are borne on rather long curving, reddish stalks set with fine hairs The long, narrow leaves have a cinnamon-coloured tomentum. Shown by Mr. Gerald Loder.

RHODODENDRON AUGUSTINII.—A small truss of bright mauve flowers of wavy outline which have a few dull spots on the upper segment. The leaves are relatively small. Shown by Dame Alice Godman.

RHODODENDRON CAMPYLOCARPUM × DR. STOKER.—The trusses have much in common with those of R. campylocarpum, and their clear yellow colour is enhanced by a bright carmine blotch at the base and small spots of the same colour on the upper segment. Shown by Mr. K. M'Douall, Logan.

TEMPLETONIA RETUSA.—This was the rarest and most uncommon plant in the hall. It makes an erect, compact little shrub with ovate, entire coriaceous leaves, and bears pea-shaped flowers of a striking orange red colour. It is known in Australia as the coral bush, and was introduced in 1803. Shown by Lieutenant-Colonel Messel, Nymans.

NEW NARCISSI.

Awards of merit were given to the following new varieties:

ELEGANCE.—A pure white giant Leedsii. Shown by Messrs. R. H. Bath, Limited.

DITTY.—A medium-sized Poeticus variety. Shown by Messrs. Herbert Chapman Limited.

NENE BEAUTY.—A good Incomparabilis variety. Shown by Messrs. R. H. Bath, Limited.

PARAMOUNT.—A fine Incomparabilis variety.

ROSARY.—A large trumpet daffodil. Shown by Messrs. Herbert Chapman, Limited.

SCARLET BEAUTY.—A large Incomparabilis variety Shown by Messrs. R. H. Bath, Limited.

SYBIL.—A giant Leedsii. Shown by Messrs. R. H. Bath, Limited.

ORCHIDS.

DENDROBIUM MODEL MAGNIFICUM.—A very fine garden-raised hybrid containing the two species nobile and Findlayanum. The large flowers have the apical half of each segment of mauve purple colour, the labellum with a dark crimson blotch at the base, and the apex mauve purple. Shown by Baron Bruno Schröder, Englefield Green, Surrey. First-class certificate.

CYMBIDIUM GOOSANDER, WESTONBIRT VAR.—A beautiful hybrid between insigne and Merlin. The spike bore six roundly formed flowers of light rose pink colour, the front lobe of the labellum yellowish and with some red markings, the column dark rose. Shown by Lieutenant-Colonel Sir George Holford. First-class certificate.

BRASSO-LÆLIO-CATTLEYA CALIGULA MAGNIFICA.—One of the finest of the brassavola hybrids, the parents being B.-C. Cliftonii and L.-C. callistoglossa. The immense flower has broadly formed segments of rosy mauve colour, the labellum dark purple, with the margin undulated and minutely fringed, while each of the side lobes bears a yellowish area. Shown by Sir George Holford, First-class certificate.

BRASSO-CATTLEYA MARY J. S. HANBURY.—An unusually large and well coloured flower of unknown parentage, but resembling the best forms of B.-C. Vilmoriniana. Of rich rosy mauve colour on all the segments, the front part of the labellum much frilled, and the throat veined with golden yellow. Shown by Mr. F. J. Hanbury. First-class certificate.

BRASSO-CATTLEYA GRAND MONARQUE.—This is the result of crossing C. Schroederæ with B.-C. Cliftonii. The large flower is of light blush colour, the labellum having a purplish front lobe, margined with white and prettily fringed. Shown by Mr. F. J. Hanbury. Award of merit.

ODONTIODA BRACKENHURST VAR. MEMORIA J. GURNEY FOWLER.—The spike bore thirteen flowers of moderate size, but remarkable for their extremely dark crimson colour, the lip having a purplish outer zone and a bright yellow crest. The result of crossing Oda. Charlesworthii with Odm. eximium. Shown by Mr. J. J. Bolton. Award of merit.

ODONTIODA ROSALEEN.—A charming hybrid of O. Coronation, with a branched spike of thirty flowers, the segments having a broad zone of rose purple on their outer area and with spotting of similar colour on the central part, the crest on the labellum bright yellow. Shown by Mr. R. Gerrish. Award of merit.

A SPRING FLOWER SHOW

THIS show, arranged by Messrs. Austin and McAslan, was held in the M'Lellan Galleries, Glasgow, on March 31st and April 1st last, and was wonderfully successful in attracting numerous exhibitors and spectators, giving great encouragement to the promoters to attempt another and greater display in the near future. One of the outstanding features of the show was a comprehensive collection of forced shrubs, plants and bulbs, staged by Messrs. Austin and McAslan. This collection was arranged on the floor in the form of three main groups or pyramids, point and distinction being achieved by the use of Japanese cherries.

Besides providing a gorgeous feast in colour and form, it also conveyed a valuable object lesson for such as have to provide a succession and quantity of flowers throughout the winter months.

Constructed by the same firm and forming a charming feature of the show was a miniature rockery. This was composed of water-worn limestone and built in the form of a natural outcrop.

Sir John Reid of Ardencraig, Bute (gardener, J. Davidson), set up a fine collection of narcissi in forty kinds, comprising old and new sorts and represented by excellent flowers.

The object of this collection was manifold, in that it afforded material for comparison to the experts and yet was sufficiently pleasing in aspect to attract and maintain the interest of the ordinary lovers of these beautiful flowers.

Adjacent to, enhancing and assisting in the objects aimed at in Sir J. Reid's exhibit, was another collection of narcissus, staged by Messrs. Austin and McAslan, and this group contained many new and unnamed seedlings of surpassing merit not yet on the market.

The same firm also set up an uncommon and interesting collection of muscari in twenty-seven pots. Prominent varieties were: botryoides, albus, and Blue, latifolius, Palleas, neglectum and commutatum.

Mr. R. Paterson, Stamperland, Cathcart, exhibited a group of orchids from the noted collection which gained for him a gold medal and first-class recommendation at a recent R.H.S. meeting. It was composed of odontoglossums, cypripediums, cymbidiums, etc. in a suitable setting of palms, ferns and moss.

Two small groups of Primula obconica were shown by Lady Muir, Doune (gardener, Mr. W. McCarrell), and were tastefully arranged in association with Primula malacoides, palms and pteris ferns.

There were numerous amateur exhibits, and keen competition resulted in the various classes, which augurs well for any future shows of this kind held by this enterprising firm.

FUNGICIDES FOR PRESENT USE

(*Continued from page 224.*)

SULPHIDE OF POTASSIUM OR POTASSIUM SULPHIDE.

COMMONLY known as "liver of sulphur," this is an extremely serviceable outdoor fungicide which may be used on a variety of plants for many kinds of diseases. Three points should be borne in mind: (1) It is malodorous, and should not, in consequence, be used close around a dwelling-house. (2) It badly discolours white paint, and is therefore unsuitable for use in vineries and greenhouses. (3) It will stain flowers. With these restrictions potassium sulphide may be used during spring, and after the flowering or fruiting season of any subject requiring a fairly powerful fungicide.

To obtain maximum benefit from the spray it should be freshly prepared, and the proper strength for general use is half an ounce to the gallon of water.

Place the required amount of sulphide in a stone or earthenware jar and stand the jar in a saucepan of water. Place the pan on a fire and allow to boil until the sulphide is completely dissolved. The boiling should be done outdoors or in a shed removed from the dwelling; the obnoxious smell would be unbearable in the house.

Allow the solution to cool down considerably and then stir in the whites of eggs at the rate of one egg to 8 ozs. of sulphide, the object being to make the fungicide adhesive to foliage and stems. Stir the preparation into the requisite quantity of luke-warm water and spray forthwith. Practically all mildews, chrysanthemum rust, carnation leaf-spot, sweet pea leaf and haulm diseases, lily fungus, onion mould, peach-leaf curl, anthracnose of currants, rose-leaf rust and sclerotinia diseases may all be treated with the spray.

COPPER-SULPHATE FUNGICIDES.

The use of copper sulphate is of importance to practically all outdoor gardens, whether devoted to vegetables, fruits, ornamental shrubs or flowering plants, and some of the copper fungicides are serviceable under glass, particularly for peach and nectarine trees, for various indoor shrubs and for tomatoes.

Copper sulphate alone, dissolved in water, makes a spray so powerful that it can only safely be used on dormant life. The object of mixing lime, soda or other substances with the copper is to reduce without destroying the potency of the copper salts, thus making a spray which is sufficiently powerful to kill the diseases of plants without inflicting serious injury on the leaves and young growth.

While using the term "to kill" it may be advisable to qualify it by adding —or check, for not even copper-sulphate sprays can kill a fungus which has gained a foothold among the inner cells and tissues of leaves and stems, and the greatest service it renders is to prevent the spores gaining such a foothold. This obviously means that the spray requires to be applied before the fungus develops, and in order to ensure this some knowledge of the nature and life-history of the fungus concerned is necessary.

Ignoring for the present the winter washes, it may be serviceable to describe

BORDEAUX MIXTURE

and to take note of a few diseases for which it may be successfully used, for it is certainly among the most serviceable of present-day fungicides.

Copper sulphate alone, as has already been stated, is too hot or caustic to be used on growing foliage, but by mixing with a certain proportion of lime the caustic properties of the copper sulphate are toned down, and that mixture is the Bordeaux mixture which became so widely popularised by the war-time aid of Ministry of Agriculture propaganda as the greatest preventive of phytophthora disease in potatoes. The important points are to know the purity of the copper sulphate and the caustic strength of the lime. The theoretical proportions should be 1lb. of copper sulphate and 1lb. of lime to five gallons of water, but in consequence of liability to variation in strength it is customary, when making, to test the liquid with litmus paper.

First the copper sulphate is placed in half the water to dissolve, using a wooden tub for the purpose. The lime is vigorously stirred into the other half of the water in another vessel, and, after all solubles in the lime have dissolved, time is allowed for the solids to settle, leaving clear lime water above. This clear lime water is then slowly poured into the copper-sulphate solution. Allow this mixture to settle down, and then place a piece of blue litmus paper in the solution. If it remains blue all is well, but if it turns red more lime water must be added.

There are, happily, several very reliable Bordeaux pastes upon the market which are mixed in strictly accurate proportions and require only to be diluted to the proper extent by the addition of rain water and, as so frequently urged, it is infinitely wiser to take advantage of such convenient preparations than to run any risk of damaging plants with a faulty home-made spray.

The principal summer use of Bordeaux mixture is upon potatoes for the purpose of preventing attacks of potato disease (Phytophthora infestans). The spores of this fungus are liberated and blown about to settle on the growing crops, usually between the end of June and middle of July. The spores are capable of lying dormant until favourable atmospheric conditions, which are a combination of warmth and moisture, facilitate germination. The aim should be to coat over the whole surface of the potato haulm, upper and under surface of foliage, and stems, with a thin film of the Bordeaux spray, and if this is done before the spores have become active they will be destroyed. The spray does not remain effective for a prolonged period, and it is frequently necessary, especially if thunderstorms and sultry weather prevail, to spray twice during July, and perhaps even a third time in early August.

BURGUNDY MIXTURE.

This is a combination of copper sulphate and sodium carbonate, which, in plain language, is washing soda. Its capabilities and purposes are the same as those of ordinary Bordeaux mixture, and although claims have been made which purport to show distinctions between the two, the sensible course is to look upon Burgundy mixture as a convenient alternative when from any cause a reliable supply of lime is unavailable for the making of Bordeaux mixture. It usually requires double the weight of soda to reach the same effect as lime. With the prepared pastes already recommended the circumstances which might necessitate the substitution of soda for lime are less likely to occur that was formerly the case.

WOBURN BORDEAUX EMULSION

is a copper-sulphate preparation made to a special formula prescribed by the late Spencer Pickering during his connection with the Woburn Experimental Station. It is held to be capable of killing caterpillars and various other insects, as well as checking the fungoid pests for which ordinary Bordeaux mixture is used. Potatoes occasionally suffer from insect as well as fungoid pests, particularly the Lygus bug and the potato frog fly, and when these are discovered it is well to use Woburn Bordeaux Emulsion. In the usual course, however, it would be among roses, chrysanthemums and also euonymus that the emulsion will be most required.

These copper sulphate mixtures cannot claim the same power over fruit tree diseases that plain copper sulphate has in winter, and if good use is made of the latter in the proper season there should be no cause to spray again for fungoid pests in summer. The mixed sprays, however, are frequently serviceable in combating cucumber mildew (Plasmopara cubensis), a disease which also attacks melons. The under sides of the foliage should be sprayed, but it must not be used on fruiting plants unless it can be guaranteed that the fruits of cucumbers will be carefully peeled. Cherry leaf scorch (Gnomonia erythrostoma) is another troublesome disease which Bordeaux mixture will hold in check. The disease frequently attacks cherries growing on harsh gravelly soils. It is identifiable from the shrivelling and browning of the leaves, which, however, do not fall from the tree but frequently remain hanging throughout the winter. One spraying shortly before the trees burst into blossom and a second immediately after fruit has set will usually prevent a recurrence of the trouble.

The yellow spot disease of tomatoes (Cladosporium fulvum) may be prevented or checked by spraying with either Bordeaux mixture or the emulsion. Gather ripe fruits before spraying, and immediately wipe the remainder, or at least the larger green fruits before the spray dries.

L. I. ATRIS.

GARDEN TECHNIQUE

THE GREENHOUSE

EARLY TOMATOES.

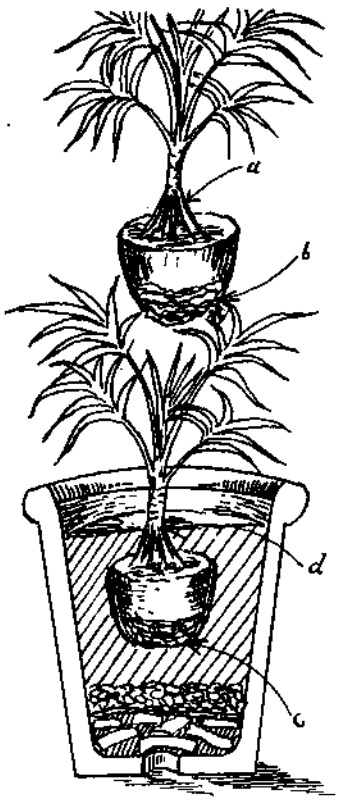
WITHOUT a certain amount of heat it is not possible to obtain very early ripe tomatoes. Heat is essential, a naturally early fruiting variety is also necessary. The early sorts are generally small, but of good shape and numerous on the plants. Sometimes the very early plants die off wholesale while small, and mostly soon after they are transplanted. This often occurs when the seedlings are transplanted into a very finely sifted soil. A rather lumpy soil with some old mortar rubble in it obviates this trouble usually. Frequently when a too fine soil is used there is loss of seedlings in cases where amateurs raise young plants in their greenhouses during the latter part of February and throughout March. I am writing these notes for the benefit of amateurs who have not had much experience and wish to get their plants forward with the aid of a moderate heat in the greenhouse. Undoubtedly the earliest crops are grown in large pots—10in. 11in. and 12in. ones—and are duly repotted from the seedling stage. We will suppose that the young seedlings are ready for transplanting; instead of doing this into pans or boxes pot them separately into quite small pots. Place one crock in the pot and a small quantity of soil; put in the seedling and almost bury the stem to the seed leaves, but do not press the soil against the stem hard enough to bruise it. Only apply tepid water to prevent the drooping of the plants. Repot again into 6in. pots and then into the large ones. Three parts fill the latter at first, and afterwards top-dress and feed. High, sunny shelves at the back of a lean-to house or on the stage near the front glass are ideal positions for the fruiting plants.—G. G.

BOXING SEEDLINGS.

THIS constitutes a big business in the spring-time. In nearly every garden there are thousands of seedling plants requiring more space to grow in. It is a time of the year when many things need attention at the same time; if neglected, seedlings, growing in a crowded state, become weakly and they rarely recover normal strength. The plan of transplanting the seedlings in boxes prior to their final planting in the open border is a good one. All the seedlings may not be required, then pick out those growing most thinly and others near the sides of the pans or boxes—as such, being more isolated, are sturdier and more vigorous than those growing near the centre, and perhaps, in a very crowded state. Of course, all young seedlings intended for the flower garden should receive this attention; but those for greenhouse and conservatory decoration should be even more carefully treated in this way. Tuberous begonias possess quite large leaves in a seedling stage; if left unduly crowded for a week or ten days, many may be lost through overcrowding. These remarks apply to seedling gloxinias, too. Here, again, all the seedlings may not be required, so we must deal with them at an early stage and select the strongest. The boxes should be filled with good old loam and well decayed leaf-soil in equal proportions and a free sprinkling of silver sand. The seedlings are almost rootless at this stage, each one merely possessing a thin thread-like root. Each seedling should be balanced on the point of a thin stick, dipped into water every time it is used to raise a tiny plant from the seed pan. The seedlings are too small to be handled freely and much too tender. It is only necessary gently to press the delicate root into the surface of the newly prepared soil with the point of a second thin stick. Then place the filled boxes in a shaded part of the house, and in a short time these young seedlings will be strong specimens. Allow a space of 2ins. between the seedlings. As other kinds of seedlings become fit transplant them in a similar way, then pot each one singly.

REPOTTING PALMS.

THE date palm, Phœnix dactylifera, can be grown very successfully in a greenhouse where heat is only used to exclude frost. Other varieties should be grown in a warm greenhouse or in a heated conservatory. I refer to palms so, because many lovers of the plants try to grow numbers of palms in an unheated house; after a short time the fronds begin to turn yellow and then the inexperienced think re-potting is necessary, whereas it is warmth and moisture that they require.



But many thousands of palms do require repotting every year—not necessarily the same specimens—and the present time is a suitable one for the carrying out of the work. As stated, cold causes the leaves to turn yellow, so also do they become yellow when the plants are starved—lacking nourishment. Palms are frequently placed in halls, corridors and even dwelling rooms. They should never be left in such positions for a long time, but be changed frequently, as cold draughts and a dry atmosphere are bad for them. Newly-potted specimens should not be used in these positions; wait until new roots have formed and taken possession of the fresh compost. A rich, fibrous loam, inclined to heaviness, rather than lightness, is an ideal one to use. Rotted manure may be added, but not fresh; bonemeal is also beneficial. Palms generally form many roots in the bottom of the pots, often causing the plants to lift bodily out of them. A little drainage, but very efficient, should be the rule, and very firm potting. At *a*, a plant is shown badly in need of repotting; the roots *b* should be disentangled so that the base, *c*, may be placed low down in the new soil and the top roots, *d*, buried, but not any portion of the stem. Water carefully afterwards; do not apply liquid manure the first year.—G. GARNER.

ZONAL PELARGONIUMS FOR FLOWERING NEXT WINTER.

MANY owners of greenhouses like to have zonal pelargoniums flowering during the winter months as well as in the summer. To rely solely upon the summer-blooming plants for the winter display would mean much disappointment. April is an ideal month in which to propagate the cuttings. The latter should be inserted singly in small flower-pots so that when rooted they will not be disturbed when first repotted. Only use fibrous loam, a very small quantity of leaf-soil and some coarse, clean silver sand for the cuttings; the loam must be lumpy, not sifted too finely. Medium strong shoots make the best cuttings, and these should possess about five main leaves, the two lower ones being removed and the stem cut off through the bottom joint with a sharp knife. Insert each cutting near the side of each pot, water and place them on a shelf in the greenhouse, shading only from bright sunshine with sheets of paper. Directly the cuttings are well rooted repot them, and again as they need more rooting space, until they occupy 6in. pots, or 7in. ones at the most. The first named are the best in which to flower the plants, as the latter can be well fed during August and September. When established in their flowering pots the plants should be placed on a bed of ashes in a sunny position outside. While there remove all flower-stems and stop forwards shoots to induce a bushy habit. Six weeks prior to the date when flowers are needed stop the practice of removing the flower-stems. Place the plants under glass about the middle of September. I strongly recommend the majority of the varieties to be of the single-flowered section, as the trusses do not damp as much as those of the semi-double. Use bone-meal in the summer composts. —CHRISTCHURCH.

FEEDING VINES AND PEACHES.

AMATEUR cultivators are always very eager to grow fine bunches of grapes and large handsome peaches. To produce such it is necessary to feed the vines, not only with suitable food but at the right time and in proper doses. These matters often puzzle amateurs, and, in consequence, those who are not experienced either fail to apply sufficient food or deluge the borders with very strong manures. In the case of both vines and peaches well diluted farmyard manure or that of a similar nature, made in tubs or cisterns, is ideal. There are special concentrated manures, sold by firms advertising in this journal, suitable for these fruits as well as others. In every instance, when a stimulating food is to be applied the soil should be thoroughly moistened first with clear water. The right times to feed vines are, first, when the berries have just been thinned; second, directly the stones in them have hardened; and third, the moment that the berries begin to colour for ripening—three times during the growing season. Peaches should be fed, first, directly the first thinning is finished and the young fruits are about the size of Barcelona nuts; second, when the stones in them have hardened; and third, when the fruits begin to soften for ripening. The stones require a period of three weeks in which to harden, and during that time the fruits do not swell much, so it is unwise to force them by extra feeding.

FLOWER GARDEN

CHRYSANTHEMUMS.

RUST on the leaves may appear at any time now. There is more danger of this pest infesting the plants in gardens where the plants are not subjected to a slight artificial heat as occasion arises. Every cultivator should closely examine the plants, on the under sides of the leaves especially, as it is there that the rust is to be found. As its name implies, rust is dark reddish brown in colour, appears in single or grouped clusters which, if touched, will discolour the fingers. Applications of sulphide of potassium will entirely free the leaves from the disease. It was found on our weed, the plantain, I believe, more than a century back, so if such weeds are found growing in dry places in or near the garden they should be destroyed before the chrysanthemums are placed in their summer quarters. The rust spores, when dry, are readily blown from plant to plant. The sulphide should be retained in rock form in a bottle, tightly corked, till required for use, as it soon loses its strength if exposed to the air. Half an ounce, dissolved in 1 quart of water, will do well for use at the rate of 2 wineglassfuls to 1 quart of clear water. Dip the young plants in this towards the end of the day. The following morning the leaves will be dry and the rust killed. To strengthen the young plants at this time they should be placed on high shelves close to the roof glass and receive plenty of air on fine days. Before the young stems become in the least drawn up and weakened, they should be transferred to a cold frame, and in it receive abundance of air.—HANTS.

ZINNIAS FOR EXHIBITION.

THE double-flowered varieties are grown more extensively every year for exhibition, especially by amateur cultivators. In my district they are so grown year after year, and so well that I think it would be difficult to find better blooms in any other part of the country. Zinnias are impatient of very wet soils and of dull, sunless weather. Furthermore, the plants receive a very serious check if they are transplanted when attaining to a large size. Avoid very wet soils, late transplanting and select the hottest position in the garden. Most of the shows at which zinnias are staged are held from the third week in July to the first week in September, mid-August being the ideal time and to have the blooms at their best the plants should be raised in a greenhouse or frame at the beginning of April. The plan I recommend is the following one: Sow the seeds in 3in. pots filled with a good compost of fibrous loam, leaf-soil and a small proportion of builders' mortar rubble. Sow several seeds in each pot, thin out the resultant seedlings to one, repot if necessary into 6in. pots, give frame treatment until mid-May; then gradually harden the young plants and finally plant them early in June. Prepare the soil in a warm part of the garden, deeply dig it and bury a liberal quantity of rotted manure. If the soil is naturally clayey, raise the bed 4ins., surface dress with leaf-soil in this case and well rotted manure if the soil is light. Shading of the blooms is neither necessary nor advisable; timely disbudding in the case of side growths is, and also careful staking. Feed but do not apply strong doses of manure.—G. GARNER.

VEGETABLE GARDEN

EARLY BRUSSELS SPROUTS.

THE earliest sprouts are generally ready at the end of September. They are not required before that time, as the summer vegetables have been available. Furthermore, the sprouts are always sweeter when they have been touched by frost or, at least, been exposed for a time to very cold weather. The earliest sprouts are generally borne on plants raised eleven months previously. At the present time autumn-raised plants will be growing in their final quarters or in nursery beds. If in the former, they should be examined and, on the first occasion that the soil is found fairly dry, tread the soil around each plant and immediately after draw up some loose earth to the stems, right up to the basal leaves. Firmness of soil is a very important point in the successful cultivation of Brussels sprouts, and yet so many growers do not pay sufficient attention to it. The rooting medium should be firmed when the soil is dry. Successful cultivation means stems well clothed with very firm sprouts. Loose ones are almost useless. Firm sprouts remain sound and keep well; they are the sweetest, too. Spring-raised plants should be grown on steadily, not in great heat, but in a greenhouse temperature till the first week in March, then in a cold frame till the end of the month, being hardened and planted in firm ground about the middle of April.

TOMATOES FOR OUTSIDE BORDERS.

WE do not know, of course, what kind of weather will prevail during the coming summer. If we did we should plant out more, or fewer, tomato plants accordingly. But during the past forty years I have observed that three summers out of five are fairly favourable, and in adverse seasons we rarely lose by having a few plants in outside borders. A great deal depends upon the cultivator, too. He must be well prepared with strong plants by June 10th in the southern and June 15th in the northern counties. It is, as a rule, safe to plant on these dates if the stock has been duly hardened. Pot-bound plants, if healthy, are an advantage, as the first trusses of fruits soon set on them. But if large numbers are to be planted out, it is best to do without pots throughout. I have found the following a good plan: The seedlings, raised late in March, are transplanted 4ins. apart in boxes 5ins. deep in due course. They are given warm greenhouse treatment until the middle of April, then the boxes are transferred to a cold frame which is covered every night to exclude cold air and actual frost. In the meantime a special bed is prepared on the south side of a wall by putting down a thin layer of sifted ashes, then one of rotted manure and finally 3ins. of good compost. Early in May the tomatoes are planted 6ins. apart in this bed, the soil well firmed and watered. For several days and nights a covering of mats is necessary, these being supported on stakes, afterwards night coverings are sufficient. When finally transplanting, the whole of the soil can be moved as the roots have taken possession of it down to the ashes and the plants do not receive any check.—CHRISTCHURCH.

PLANTING OUT EARLY VEGETABLES.

IN numerous instances where very heavy, cold soils obtain, gardeners make it a rule every year to raise an extra number of young vegetables under glass, mostly in cold frames, and in due course plant them in their permanent positions. These gardeners succeed because they pay very close attention to the work, and reap early crops of tender produce. Amateur cultivators may also succeed. I daresay hundreds of readers of THE GARDEN now possess nice stocks of young plants in boxes or frames; it is a critical stage and time of year for such plants, as they have been sheltered and are, in consequence, tender. To expose them fully without due preparation would result in such severe checks as to make the plants almost useless, and thus later-sown seeds would prove the most satisfactory. Autumn-raised cauliflowers are now in cold frames; these should be planted out about mid-April. Young cauliflowers raised in a little heat this year must be given cold frame treatment till the end of April. From the middle of this month to the end will be suitable for planting out box-raised onions, and May 20th for leeks. Lettuces should be planted out in sheltered borders late in April, and early in May in open borders. Runner beans the first week in June, and marrows the second week in June. It is most helpful if tiny but bushy branches are stuck in near the plants and, generally, advantageous if tiny ridges are formed north to south and the plants are placed on the west side of each ridge. Later on, when the ground is hoed, the ridges are levelled.—BOURNEMOUTH.

MAINCROP PEAS.

SOMETIMES one notices that little difference is made between the method of sowing early and maincrop peas. While one may err somewhat by sowing the former more generously if one starts in March, in order to allow for failures and depredations by birds, mice, etc., the case with maincrop varieties is different. Many of these are not sown until April or early May, and at that date it is a mistake to sow seed thickly without having regard to the robustness of the sort. Peas of the type of Duke of Albany and Alderman, noted for their vigorous constitution and large haulm, obviously need more room for development than do some of the early dwarfs, and to cramp the taller growing varieties in the matter of room at the beginning is never satisfactory. It is sometimes pointed out that peas found to be sown thicker than was intended can be thinned out afterwards, but I have never found it easy to lift once the roots have got hold of the soil, without disturbing roots of the remaining. It is, I submit, better in the case of robust varieties to give them room from the start and avoid the need for lifting any of them.—W. LINDERS LEA.

MISCELLANEOUS

MOWING OLD AND NEW LAWNS EARLY IN THE SEASON.

SOILS vary in different parts of the country, and, of course, the grasses growing in them vary too in quality. The grass improves or deteriorates according as the lawn is cared-for or neglected. I am now referring to lawns that have been well formed in the first instance, during recent years. But the great majority are lawns indifferently made and clothed with mixed grasses, many of them of a coarse nature. Even such lawns can be very much improved by good management—feeding, mowing and cleaning. During the first few weeks, old, neglected lawns should be cut rather low down; if this is not possible at the first cutting, it should be at the second; then the young grass, as it springs up, will not be mixed with the wiry stems of coarse and dead grasses. The latter should be cleared off the lawn as soon as possible. Note how the mowing machine has been set for this severe cutting and raise the blade a little for subsequent cuttings, so that the new grass will be cut about 1in. above the old, thus, in a few weeks' time, ensuring a nice green lawn of thickly grown grasses. On the other hand, new grass raised from seeds should be cut high at first, and then gradually to the normal height. Coarse weeds and tufts of coarse grasses should always be rooted out cleanly and the holes made filled up with sifted loam. If left, such grasses and weeds will spread. In June, all except lawns on very rich soil will be improved by a dressing of bone-meal—2 oz. per square yard.—G. G.

What users are saying about The J·P SUPER

ALL UNSOLICITED.

From a Lawn Owner:
"It is the easiest machine to work devised and renders a petrol-driven motor a superfluity."

From a Lawn Owner:
"No effort is required to push the machine, which is a 16-inch.

From a Lawn Owner:
"In addition to saving a man, our lawns are kept much nicer than ever before at much less cost."

From a Golf Club Secretary.
"I would like to register my admiration of your Mower and gratitude for at last producing something so infinitely superior to the 'plumber's jobs' in mowing machines that we have had to suffer from so long."

From a Golf Club Secretary:
"The Greenkeeper tells me it is easier, quicker and more thorough than any he has ever seen, and hopes he may never have to revert to the old type."

From a Gardener:
"It is the most marvellous machine I have had anything to do with, and have used all the best makes in my time."

"It is so simple to adjust, easy running and best all-round cutting machine I know of. It is all you claim it to be."

WORMS—AND WEEDS

TO clear these pests from your lawn, bowling or putting green:—Brush or rake away the worm casts. Scatter **Cooper's Powder Wormkiller** evenly over the turf during damp, dull, warm weather, and water the ground thoroughly. The worms will come up to the surface, and then all you have to do is to sweep them up and bury them.

The "worm cast" nuisance is over, but you still have the weeds, and other rank growth to consider. After using the Wormkiller, let the ground dry thoroughly, then apply **Cooper's LAWN SAND** which will destroy all daisies, dandelions, etc., which disfigure the lawn. Cooper's Lawn Sand also acts as a lawn food, assisting growth and distribution of the finer grasses.

Further particulars are given in our leaflet, "ENEMIES OF THE LAWN," which will be sent free on request.

TWO HANDSOME FLOWERING SHRUBS

PIERIS JAPONICA and P. floribunda, known in many gardens under the name of andromeda, have shown their beauty to distinct advantage during the past few weeks, and have proved themselves valuable acquisitions to the garden in early spring. Pieris japonica is a native of Japan, and has drooping sprays of bell-shaped flowers so freely produced that they completely cover the whole plant. All the pieris are valuable for shrubs, and this one is doubly so, as its free-growing and early-flowering habit renders it indispensable to the garden. The flowers and foliage are not so large as in P. formosa, but, unlike that species, which is only to be seen at its best in the milder districts of the south or south-west, it is fairly hardy, but should be planted in a sheltered spot where there is no chance of its foliage and flowers being damaged by winds. The young growths made after flowering are of a brilliant colour, reminding one of the Japanese maples. To appreciate the full beauty of this, one has to see plants that have attained large dimensions. One very fine specimen which has been in flower since the beginning of February is to be seen in the wild garden at Wisley, measuring approximately 12ft. high and 45ft. in circumference.

There is also a fine plant of the more common and hardier variety, P. floribunda, a native of the eastern United States. This makes a neat, slow-growing bush, eventually reaching a height of 6ft. to 9ft., and at present is covered with its erect terminal lily of the valley-like flowers. It is valuable for its early and free-flowering habit, but lacks the graceful outline of japonica.

Propagation is effected by layers or seeds Of the latter method good examples can be seen at Wisley, where self-sown seedlings are to be found growing on mossy banks near the parent bush. Layering from stools in the nursery ground is much quicker, however, and is the usual method adopted to increase the stock.

Like the rhododendrons, the pieris require plenty of moisture; and positions that suit the rhododendron, with soil of a peaty nature, or a sandy loam with which plenty of decayed

PRIMULA "WANDA"

— A.M., R.H.S. —

THE WINE-COLOURED PRIMROSE.

Raised and introduced by Bakers.

THE short history of "WANDA" is a record of extraordinary sales. In the three years it has been seriously on sale, we have sold over 30,000 plants.

Odd specimens of its wonderfully rich wine-coloured flower will appear in December in sheltered places, and from then onwards it gathers way until it reaches perfection in March. "WANDA" is the brightest of all spring flowers.

Order plants now to be sent after flowering at 8/- per dozen, carriage paid

leaves have been incorporated will prove excellent for pieris.—R. FINDLAY, *Wisley.*

TRIAL OF "ADCO" MANURE.

PROMPTED by frequent applications from gardeners and allotment holders for advice regarding effective substitutes for farmyard manure, early last year the West Sussex County Council decided to make a plot trial of the Adco process at their demonstration ground, Kingsham Farm Garden, Chichester. Supplies of "Standard Adco" and "Adco Accelerator" were obtained, the former being used for treating wheat straw and the latter a collection of garden rubbish, comprising weeds, grass, leaves, cabbage stalks and general vegetable refuse. After a few months' fermentation, both the straw and garden refuse had decomposed thoroughly and were deemed fit for use.

It was arranged to test the Adco manures on a crop of potatoes against similar plots dressed with farmyard manure. For this purpose four plots each of 4 rods were chosen, and the soil (medium loam) dug one spit deep. The manuring was carried out as follows:

Plot (*a*).—"Adco" Straw manure, 7 barrowloads (about 20 loads per acre).

Plot (*b*).—Farmyard manure, 7 barrowloads (about 20 loads per acre).

Plot (*c*).—"Adco" treated garden refuse, 7 barrowloads (about 20 loads per acre).

Plot (*d*).—Farmyard manure: not completed owing to shortage of labour.

Artificial Fertilisers:

Superphosphate, 12lb. per plot (4cwt. per acre).

Sulphate of ammonia, 3lb. per plot (1cwt. per acre).

Sulphate of potash, 3lb. per plot (1cwt. per acre).

Note.—Organic and artificial manures both applied at time of planting.

The seed selected was Scotch once-grown, the following varieties being sown at the rate of approximately 42lb. per plot (15cwt. per acre): (1) Bishop; (2) Irish Chieftain; (3) Up-to-date. One row of each variety, containing the same number of tubers in each case, was sown on each plot on May 15th.

The potatoes were lifted on October 9th, when the following results were obtained:

Plot (*a*).—"*Adco*" *Straw Manure:*

	Ware	Seeds & Chats.	Total
	Lb.	*Lb.*	*Lb.*
Up-to-date.. ..	178	49	227
Irish Chieftain ..	135	10	145
Bishop	97	35	132
	410	94	504

= 9 tons per acre.

Plot (*b*).—*Farmyard Manure:*

Up-to-date.. ..	139	32	171
Irish Chieftain ..	84	33	117
Bishop	111	9	120
	334	74	408

= 7 tons 5cwt. per acre.

Plot (*c*).—*Garden Refuse:*

Up-to-date.. ..	114	38	153
Irish Chieftain ..	110	36	146
Bishop	98	38	136
	323	112	435

= 7 tons 15cwt. per acre.

Average yield of potato crop for England and Wales for 1925 = 6.6 tons per acre.

Over £3,000
The National Rose Society will hold a Special Jubilee Show in conjunction with the Southport Show.
There will be Two Competitive Rose Sections for Nurserymen, *i.e.*—One for Nurserymen South of a line drawn across the Country from Spalding to Aberystwyth, and the other for Nurserymen North of that line and including Ireland.
Spaces 15 ft. x 10 ft. will be provided inside the Showground for Exhibits of HORTICULTURAL SUNDRIES at £5 per space.
Schedules and plan of Showground, showing the positions of the spaces for horticultural sundries and the Official Guide Book of Southport, may be obtained post free from THE SECRETARY, FLOWER SHOW, TOWN HALL, SOUTHPORT.

FLOWERS and VEGETABLES
Flowers and Vegetables will not give of their best unless they receive a dressing of Nitrate of Soda.
The difference can be seen in one week.
Write for pamphlets, entitled, "Successful Gardens for Every Amateur," "The Manuring of Orchards and Fruit Trees," supplied gratis and post free by THE CHILEAN NITRATE COMMITTEE, Friars House, New Broad Street, London, E.C. 2.

B.D.H. SOIL TESTING OUTFIT

INDISPENSABLE TO THE GARDENER AND FARMER

It is well known that one of the first and fundamental principles in regard to soil treatment is to ensure a sufficiency of lime, for without this essential soil ingredient satisfactory crops can never be obtained, as the soil is, or soon will become, sour. By means of this handy outfit it is possible to find out in a few moments whether a given soil requires treatment with lime in order to remove sourness, and thus

TO ENSURE HEALTHY CROPS AND BETTER PRODUCTION

THE B.D.H. SOIL TESTING OUTFIT
Needs no technical knowledge—A child can use it.

The set comprises:—
SPATULA
SPECIAL PORCELAIN BOAT
BOTTLE OF B.D.H. INDICATOR
Complete in cardboard box, with directions for use.

BRITAIN'S BEST BULBS

GOLD MEDAL R.H.S. 23rd MARCH, 1926. **ALL HOME GROWN.** GOLD MEDAL R.H.S. 13th APRIL, 1926.

DAFFODIL LOVERS SHOULD PLACE THEIR ORDERS *NOW*.

A FEW GEMS - To ensure the best results we advise planting by the end of August, although this may be continued later. . . The following are some of the choicest varieties :—

ACE OF DIAMONDS (Poeticus).—This is undoubtedly the finest all-red-eyed Poeticus yet seen. Each, **35/-**.

BERNARDINO (Incomparabilis).—A very bold and beautiful flower; large creamy perianth, suffused deep orange; a good free grower. A.M. Each, **1/3**; doz., **12/-**.

CROESUS (Incomparabilis).—This famous flower is still the finest richly coloured Incomparabilis. Each, **5/-**.

DAOTYL (Poeticus).—In size, substance and quality, this is the high water mark in POETS; a very vigorous grower. Each, **18/-**.

DONAX (Incomparabilis).—One of the late Mrs. Backhouse's remarkable introductions. A most distinct and striking flower, having a broad yellow perianth and wide orange-scarlet cup. Each, **4/-**.

EVEREST (White Trumpet).—The flower is pure white throughout and is of fine waxy texture, having broad, well formed perianth, standing at right angles to the trumpet. Award of Merit, 1922. Each, **£2 10s.**

FESTIVE (Incomparabilis).—A very beautiful and brilliantly coloured flower; overlapping but pointed perianth, shaded yellow towards base of segments; long crinkled crown, flushed clear orange-scarlet. Each, **12/6**.

FIRETAIL. Without doubt the finest red-crowned Barrii yet seen. A.M., R.H.S., 1920; F.C.C., 1922. Each, **10/6**.

GOG (Yellow Trumpet).—A very early and very vigorous Yellow Trumpet; a fine long stem, carried very erect. Each, **5/-**.

GOLDEN PEDESTAL (Incomparabilis).—This is without doubt the finest self yellow INCOMPARABILIS yet seen; a flower of the most perfect form and quality. Award of Merit, R.H.S., 1922. Each, **£9**.

IRISH PEARL.—One of the very best Giant Leedsiis ever raised from MINNIE HUME, crossed with a Trumpet. Each, **3/-**; per dozen, **30/-**.

JERSEY CREAM (Bicolor Trumpet).—One of the most beautiful and distinct bicolors on the market. The bloom has great substance and waxy texture; white perianth, with well flanged trumpet. Each, **15/-**.

LADY SACKVILLE (Giant Leedsii).—This we consider one of the finest varieties raised by the late Mrs. Backhouse. It is remarkably early, of the purest white, excellent form, and fine lasting qualities. Each, **45/-**.

MAGOG.—A splendid, graceful, self-golden giant Trumpet of immense stature and vigour. Somewhat after KING ALFRED in style, but larger. Will grow where KING ALFRED fails. A.M., 1922. Each, **4/6**.

MARKET GEM (Giant Incomparabilis).—A flower of excellent form and substance and a very profuse bloomer, carrying its flowers well above the strong, broad foliage. A very vigorous plant, and an excellent garden variety and splendid market flower. This variety was one of the three which won the "Walter Ware" Challenge Cup for market varieties, at Birmingham Show, 1921 and 1922. Each, **1/-**; per dozen, **10/-**.

MARKET GLORY (Giant Incomparabilis).—A very large and very tall flower, having rich deep lemon-yellow perianth and large, long crown, flushed throughout with glowing coppery red-orange; a gorgeous decorative flower, and one that we shall hear of a good deal in the near future. Each, **35/-**.

SELINA MALONE.—Certainly one of the finest Bicolor Trumpets yet offered. Flowers of enormous size, yet of beautiful quality, having grand, broad, smooth white segments and noble, clear soft lemon trumpet; grows with great vigour. Each, **7/6**.

SILVER FOX.—A very large and striking Giant Leedsii with spreading white perianth and large, well expanded crown, which is more or less reflexed at the brim; the crown opens sulphur, but very soon the whole flower passes to pure white. Very tall and vigorous; a fine effective garden plant. Each, **6/6**.

ST. DOROTHEA (White Trumpet).—This variety caused a great sensation when first exhibited at the Midland Daffodil Show; at that time it was described in the Press as "a white edition of ROYALIST," and we ask for no better praise; it is of the purest white throughout, with broad overlapping perianth; it is probably more dainty than vigorous; certainly one of the most refined varieties we have ever seen. One or two bulbs to offer this season. Each, **£5 5s.**

TENEDOS (Giant Leedsii).—The sensation of 1921. Both in London and Birmingham this variety came in for more praise than any other variety, and rightly deserved it. When first opened the crown is primrose, but passes soon to pure white; of first-rate texture. First Class Certificate, Birmingham, 1924. Each, **£5 10s.**

WHITE EMPEROR (White Trumpet).—From the standpoint of the florist and exhibitor alike, this superb flower is unrivalled. It has attained in the marble-like smoothness and solidity of its texture, and classical purity and perfect symmetry of its outline, a point of excellence beyond which it is difficult to imagine much improvement. For many years it will be indispensable to all who aspire to the front rank as exhibitors, and to the hybridist it will be no less essential; it is a very free seeder. Each, **30/-**.

WHITE STAR (Barrii).—A distinct and very beautiful flower of decorative type, spreading star shaped pure white perianth of good substance, 4ins. in diameter; shallow crinkled crown of a beautiful, cool, greenish primrose. A very charming and refined flower, plant of good constitution. Each, **2/6**.

WHITEWELL (Incomparabilis).—Although a modest price, this variety has still to be reckoned with where a flower of good quality is needed; it carried off first prize at the Daffodil Show on April 12th, 1926, although it was up against the newest and most expensive varieties. Per dozen, **8/-**.

COMPLETE LIST WILL BE FORWARDED POST FREE ON APPLICATION.

DONARD NURSERY Co. (WILLIAM SLINGER, Sole Proprietor) **Newcastle, Co. DOWN**

A Prolific Garden

cannot be maintained without the aid of some kind of manure. Stable manure is now scarce, and is bulky to cart and spread on the land. No artificial will altogether take the place of natural manure, but a good well-balanced fertiliser, used during the growing season, is a wonderful aid in producing high-class garden crops. No fertiliser is cleaner, more effective, or economical than

PEARSON'S CHEMICAL MANURE

which is compounded from the purest chemicals. It contains every element necessary to plant life which is not present in any ordinary garden soil. A glance at the analysis will prove that this manure is as cheap as any on the market, while nothing can beat it in ease of application and results.

ANALYSIS

PEARSON'S "CHEMICAL MANURE"
(ARTIFICIALLY COMPOUNDED)

Contains at least 11·79 *Phosphates, soluble and insoluble;* 6·68 *Potash;* 5·44 *Nitrogen* (*Ammonia Nitrogen* 4·56, *Nitric* 1·88).

Per cwt. 28/-, ½ cwt. 13/- carr. paid. ¼ cwt. 7/-, 14 lb. 4/6, 7 lb. 2/9, carr. forward.

NEW HARDY CRIMSON BROOM

AT Chelsea Show (1925) *the King said, "That red Broom is certainly very striking." This was the new crimson Broom "Dorothy Walpole," which received the unanimous Award of Merit from the R.H.S. as well as other distinctions in London and on the Continent.*

In the "Field," a well known ex-Curator of Kew Gardens wrote: "The richest coloured Broom known is one named 'Dorothy Walpole.' It is as hardy as the common Broom . . . and is very free-flowering . . . the colour is rich velvety crimson . . . more attractive than any of the coloured Brooms yet seen." The colour far surpasses Cytisus Dallimorei, and the growth is as vigorous as C. Andreanus; it requires no special treatment nor any kind of protection whatever—just a hardy shrub for ordinary garden soil in any part of the British Isles, however far north.

A Vice-Chairman, Floral Committee, R.H.S., wrote: "Everyone who has seen my plant has been astonished at its warm glowing red," and from a lady in Devon: "I am so delighted with the Broom 'Dorothy Walpole.' It has done splendidly and is like a sparkling gem in the garden—one mass of flower."

Strong pot-grown plants now ready for planting out, to flower in May, 12/6 each. Carriage paid rates to any station in Great Britain or Ireland: One plant, carriage paid, 15/-; two plants, carriage paid, 28/6; three plants, carriage paid, 41/-; six plants, carriage paid, 79/6.

Coloured illustration sent on application if THE GARDEN *is mentioned.*

NOTES FROM MY GARDEN

THERE surely has never been such a bulb year as this. The weather on the east coast of Scotland has certainly suited them, for daffodils and early tulips are in full blaze and of excellent size, particularly those naturalised in grass, and the same applies to fritillaries and chionodoxas. Even a Crown Imperial is fully out in a sheltered corner, and this is extraordinary in our cold climate. Usually, we find that we are behind the south until the end of July, and then we begin to catch up; but the growth in the past few days has been so extraordinary that I doubt if we are so far behind as usual. Geans, which are practically native to these woods, were in full bloom on April 8th: we usually look for them at the end of the first week in May. Pyrus Vilmorinii, that last year burst its leaf buds on May 8th, has its leaves half fledged at the time of writing, April 15th. All the sorbus are early this year, so are the horse-chestnuts. In addition to the ordinary one, Æsculus indica and Æ. californica are both in advance of their time; Æsculus turbinata, on the other hand, pays little attention to the vagaries of the season and intends to open its leaves according to the calendar, for the buds are still hard.

Another genus that is noticeably fine this year is the berberis. Deciduous species and varieties have come into leaf with an amazing rapidity, and the leaves appear to be larger and better formed than usual. A rather small round-leaved variety found by Farrer and myself in Burma is flowering for the first time here, and the flower is quite remarkable. So far, they are borne singly, and almost double, about the size of a sixpenny bit, the outer petals flat, forming a platter-shaped perianth, with a tight inner ball like a yellow pea. Berberis Wallichianum is also flowering, and is undoubtedly one of the best of all the small evergreen species. The leaves are large without being coarse, very dark green above and so glaucous on the under surface as to be nearly white. The flowers are borne in short racemes and are pretty without being striking. For foliage and general shape it is difficult to beat this evergreen species, and it should be far more widely grown. Berberis undoubtedly grows best with me on a steep bank where the drainage is all that it should be and where they get a maximum of sun. Provided that the soil is not too light, what are difficult positions for most shrubs seem to suit them; but they must be given a fair start, with the soil broken up for a considerable depth below them, so that their roots can escape from the parched surface and so can anchor the plant with the tips of its roots in cool earth or rock. I usually give them a heavy mulch of leaf-mould the first year and then leave them to their own devices, with the exception of an annual hoeing about this time of year. I have never found this treatment fail, excepting in the case of some of the Mahonia group, which respond to richer conditions, and here, at any rate, like a soil and exposure suitable for a herbaceous border.

I wonder if any readers can give their experience of growing outside some of the native South African bulbs, such as tritonias, babianas, gladioli species and so on. I have had a few sent me, and I am entirely ignorant about them. Presumably, one of the great difficulties with them is that of ripening, which means annual lifting. So far so good for that is not a difficult job when the numbers are few. But are they otherwise hardy? As far as I have seen, they are all graceful in growth and flower and are distinctly lovely flowers; but about their success I am doubtful. In the Cape they must have an enormous amount of sun, and sun of a hot, scorching quality. This is probably supplied in the eastern and midland counties of the British Isles to a greater extent than elsewhere: but is even this sun hot enough? I have heard of occasional plants of all these genera being grown at the foot of a hot wall; but will a hot and rocky bank in full exposure suit them as well?

Some time ago I mentioned that I had thinned a philadelphus and Spiræa sorbifolia heavily to see if it would make them flower. In the case of the former the result has been miraculous; each bush is now heavily set with buds. There are no signs of flower buds on the spiræa, but it is a little early as yet. What it has done is to break and send out numerous short branchlets instead of the usual willowy wands. It is a very lovely shrub in its young foliage, but I wish it would produce its fine upright panicles of flower. Many of the spiræas are inclined to make ungainly, lanky bushes with age, but Spiræa arguta is an exception. Its long arching branches never become so naked as many of them with age and the small panicles of white flowers are a delight from April to June. It is one of the best for all gardens. E. H. M. C.

We have been asked to draw attention to a printer's error which occurs in the Royal Horticultural Society's Gardener's Diary. The date of the Rhododendron Society's Show is there given as Monday, April 26th, whereas it will be held in the R.H.S. Hall, Vincent Square, on the following day, Tuesday, April 27th.

AMONG THE ARTICLES IN OUR NEXT ISSUE WILL BE:

THE RETURN OF THE DAHLIA, by Norman Lambert.
SOME FLOWERING BARBERRIES, by Camillo Schneider.

THE ORANGE CORNER in the GARDEN

FASHION changes, and whereas England was formerly a country with somewhat dowdy tastes in dress and house decoration, to-day there is a most noticeable bias the other way to a love of bright colours. Of these colours none is more popular at the moment than orange.

It appears, if one is to believe the gardening journals and seed catalogues, that gardens are to follow suit and be in the fashion this year. We are told that the marigold Orange King is to be the flower of the year. For me, orange flowers have always held a fascination; the word "aurantiacus" tacked on to a flower name has a certain magical charm which is difficult to resist.

Now, when I speak of orange flowers for the orange corner in the garden, I really mean orange flowers. I am not going to admit the "salmony orange scarlet" kind, if I can help it, though in the case of sweet peas this may be rather difficult. Absolutely orange flowers are not very common, and we may have to allow a few scarlet ones to add to the gaiety of this corner. Such plants as the Oriental poppy, the scarlet lychnis and the geum called Mrs. Bradshaw. They will only enhance the blaze of colour we are going to create.

CHEIRANTHUS ALLIONII FLOWERS LATER THAN OTHER WALLFLOWERS.

I suppose that the earliest orange flowers we can find are the polyanthus and the wallflower; neither of them very startling, but still a good beginning. Then we have that early-flowering berberis which was first discovered in Chili by Darwin and named after him. Its pendent orange blossoms are followed later in the season by plum-coloured berries, beloved of the birds. By now the Crown Imperials, the lordly relatives of the fritillaries, are pushing through the ground. Though we have been able to name one or two spring flowers of orange colour, it is really not till the summer and early autumn that they are at all common. The well known orange wallflower (Cheiranthus Allionii) does not, as a rule, come into flower till the ordinary wallflowers are on the wane. But as soon as spring passes into summer, it is easy to name a score or so of orange flowers. The eschscholtzias, growing untidily at the pathside, will produce a continuous succession of flowers. Beautiful in the bud when closed at night, they are positively glorious when fully expanded in the sun. In a recent number of THE GARDEN a relative of this flower was mentioned—Hunnemannia fumariæfolia. Its poppy-like orange flowers contrast well with its glaucous foliage. The author of the article in which reference is made to this flower seems to have a special *penchant* for orange flowers, for he mentions others as well. Venidium calendulaceum, which has glowing orange marigold-like flowers, very suitable for the edge of a hot sunny border, is one; the Star of the Veldt or, as it is sometimes called, the Namaqualand Daisy, with a delicate charm all its own, is another.

Besides the giant marigold Orange King, we have the French marigolds and the African varieties, all of which are more or less orange. The marigold is one of the flowers especially dedicated to the Virgin Mary, because it is in bloom at all the festivals throughout the year which celebrate the various events of her life.

The neglected Iceland poppies must not be forgotten; some of them are a splendid orange. The nemesia, too, can be had in brilliant orange shades. It may be associated with another good edging plant, the orange fleabane (Erigeron aurantiacus). This latter might also, perhaps, find a place on the rock garden, where orange flowers are rather rare, though the delightful miniature leptosiphons can be had in this colour. Rather stiff and unnatural-looking, but gorgeous in colour, are the orange zinnias. Of orange lilies there are quite a number: Lilium croceum, so common in our cottage gardens, very effective and of easy culture; the tiger lily, with its great pendent flowers and curious little bulbils in the axils of the leaves. We must not forget the Peruvian lily (Alstrœmeria aurantiaca), with its curious fleshy roots so difficult to dig up without injury. It is a terrible plant to spread when once it takes a liking to your soil. Of sweet peas we must have a group or two in

THE LOVELY ORANGE ALSTRŒMERIA AURANTIACA.

Digitized by Google

our corner, though they are not really very orange. The best of them are, perhaps, Tangerine, Orange Scarlet, Mandarin, Gloriosa and Royal Sovereign. Among the snapdragons, Orange King will be the best for our purpose.

Of climbing plants there are not many of orange colour. The old-fashioned Eccremocarpus scaber, though usually considered half-hardy, will survive the winter in the open in Cornwall and throw up its new shoots the following spring. It has nice bunches of orange flowers which hang gracefully amid its bright green foliage which sets them off so admirably. The nasturtiums, too, would come under this category unless the Tom Thumb varieties are preferred.

As summer passes into autumn, the red-hot pokers rear their tall spires at the back of the orange corner, and the montbretias and antholyzas form great clumps here and there. Then the stiff spikes of the autumn-flowering gladioli help to add gaiety to the declining year. The varieties to choose are Orange Brilliant, Niobe and Xanthia, Orange-coloured dahlias will also find a place in the orange corner till the first frost cuts them down.

Lastly, the orange fruits: the pyracantha, which seems to set the walls of the house on fire; the winter cherry, affording decoration for the home during the winter months when flowers are scarce. This may be associated with the orange seeds of the stinking iris, so beautifully set in their tripartite pod, which opens to display them about this time of year. These, and not a few others, can be tried, and the results are certain to be most pleasant and effective. EDWARD CAHEN.

RHODODENDRONS IN THE GREENHOUSE

WHERE THEY ARE NOT ALREADY GROWN, ONE OR TWO OF THESE FRAGRANT AND BEAUTIFUL SHRUBS SHOULD BE GIVEN A TRIAL. THEY ARE NOT OF DIFFICULT CULTURE AND PROVIDE THE MOST BRILLIANT EFFECTS.

AT this time many greenhouses are made more brilliant by an occasional plant of one of the old Himalayan rhododendrons or their varieties, none of which is satisfactory outside in any but the most sheltered gardens of the south and west. The best for general purposes are either species of the Maddeni group, such as R. ciliicalyx, R. Edgeworthii or R. Maddeni, or their hybrids and varieties. There are few more economical shrubs for the ordinary greenhouse, since with fair treatment they flower year after year and live for a long time. The necessary treatment is simple, an annual repotting in half loam, half leaf-mould with good drainage, and plenty of moisture during the growing season. When the growth is finished they can be put in the cold house or a frame for the summer months. In fact, they thrive under this treatment, provided they are shaded from the direct rays of the sun. They are all the better for not being given great heat at any time of the year, as this makes them tender and forms long, lanky growths. Probably the three best varieties for the ordinary amateur are the Countess of Haddington, which opens a pale pink and turns, as the flowers age, to a blush white; Forsterianum, a particularly lovely white form with large flowers that smell deliciously of cloves; and fragrantissimum, also a pure white and with even a stronger fragrance. None of these gets out of hand and grows to a large size, which is an advantage. Those who have more room can try R. Dalhousiæ, a fine sulphur yellow, and R. Nuttalli, with fragrant tubular trumpets of white tinged with rose. Neither of them is so free-flowering as the ciliicalyx group mentioned above, and both are apt to grow leggy and so become ungainly in time. R. Maddeni itself is also inclined to lankiness, and so is R. Edgeworthii but the latter is most attractive with its thick leathery leaves and sweetly scented white flowers.

THE VERY FRAGRANT INDOOR RHODODENDRON FORSTERIANUM.

SOME UNCOMMON PEAT PLANTS

THOUGH I use the term "peat plants," this is done only as a matter of convenience. Most people will understand by that term, that it includes, for the most part, those many ericaceous subjects which, while they doubtless enjoy a peaty medium, will often do as well in any light to medium, cool lime-free loam. Indeed, none of the plants here alluded to has ever had any peat, the only addition made to the natural woodland loam being a little leaf-mould at planting time, with subsequent top-dressing of this, and grit whenever it seems desirable.

THE HANDSOME AND HARDY BRYANTHUS EMPETRIFORMIS OF PROSTRATE HABIT.

One of the most fascinating of these plants at the time of writing (end of February), is Arcteria nana. This is one of the smallest of shrubs, the Tiny Tim of the once-called andromeda clan, one which does not seem to aspire to a greater stature than a little over an inch, the spread of its wee branches only being 2ins. to 3ins. across. At the present moment this most engaging shrublet is bearing at the tips of each of its twigs ½in. racemes of white, urn-shaped flowers which smell most sweetly of honey. So generously are these blossoms yielded that they almost conceal the dark green leathery leaves, yet the whole affair could easily be covered by a breakfast cup. A. nana comes from Spitzbergen, and about three years ago it was the proud recipient of a R.H.S. award of merit.

Some two or three years have elapsed since a trio of strangers arrived here labelled respectively, Cyathodes ericoides, C. empetrifolia and C. robusta. They were experiments, for, coming from somewhere in the Antipodes, I had grave doubts as to their hardiness. However, those doubts have been dispelled, for they have withstood 20° of frost without protection and have every appearance of "making good." These curious species are said to be allied to the epachrideæ. They have a crisp, heath-like foliage, more or less suffused with a bronzy tint, and the semi-prostrate habit of a phyllodoce. In all of them the waxen-textured flowers are cylindrical and not contracted at the mouth as in the ericas. C. ericoides has these blossoms in an ivory yellow, those of the other two being white. They all have a slight fragrance, suggesting a blend of almonds and honey.

Phyllodoce (Andromeda) cærulea we have coaxed into a tolerably good temper by affording it a cool aspect facing its beloved north and by maintaining an even moisture supply during summer. This latter has been accomplished by giving plenty of leaf-mould and, in emergency, an occasional cold compress of chopped-up sphagnum. At any rate, this rather squeamish native has maintained a cheerful verdure and every season at midsummer rewards us with its blue flowers which, if not as blue as they are sometimes painted, are nearer to that colour than those of any of the smaller ericaceæ of its class.

The foregoing is said to be one of the parents of that most adorable little shrub, Phyllothamnus (Bryanthus) erectus. the other being Rhododendron Chamæcistus—hence the derivation of its new generic name. Though raised nearly a century ago, this plant is still very uncommon and one wonders why, for it is by no means difficult and it has a beauty and refinement all its own. That P. erectus may be impatient of excessive heat, drought and a dry atmosphere one must admit, but it will prosper in the humid west and north and demand no more care than one would give to any of the choicer allied subjects. P. erectus is an upright, neat shrub of about 10ins. with the hard, pale green, glossy foliage of Phyllodoce empetriformis. In the later spring the flowers appear at the extremities, half-a-dozen or more in a cluster. These are a delicate shade of rose and as the corolla is not constricted at the mouth, the five triangular segments standing out so as to give it a bell-like form, the flowers are more suggestive of some azalea in miniature than an erica. P. erectus can always claim a high place among the best of its kindred.

Also differing from the ericas in its open-mouthed corollas is a dwarf, heath-like plant from the heights of eastern Europe, Bruckenthalia spiculifolia. This species makes a dense cushiony mass of very leafy little wiry twigs, the whole rarely rising much above 6ins. and often not attaining half the height. The foliage is a bright, cheerful green and the flowers appear in June in terminal racemes rather under 1in. in length. Individually the blossoms may be small, but not in proportion to the size of the shrub. They are bell-shaped and rosy-white in colour and deserve a close-up position on a cool rock garden ledge where their very special daintiness can be appreciated to the full.

Gaultheria tricophylla is a priceless gem for partly shaded cool, rocky places, which it will cover with its charming heathy verdure of about 3ins. With mahogany-red slender stems, little deep green glossy ovate leaves and sapphire berries as large as horse beans, this winsome Himalayan is exceedingly attractive. And once it gets away in a stony, gritty bed of vegetable soil, it will creep about by means of its underground runners and so gradually colonise quite a large patch. Regarding this some may say, yes, just the carpeting for choice crocuses or erythroniums. But I contend that G. tricophylla is fully sufficient in itself, and those who can boast of having a few square feet of it well established will feel not only that they have had their reward, but that it would be what Shakespeare called "ridiculous excess" to grow anything of the above kind along with it.

If G. tricophylla must carpet something, let it companion its own kindred. For example, I once saw it clambering about the interstices of some mossy, slatey rocks among which were perched two or three bushes of G. cuneata pyrolæfolia. The latter, so bright a green, so comely and neat, and not more than about 8ins. high, were laden with their white berries—like sugar-coated pills. The two species suited each other and together they suited the place so well that I have ever since been trying to create the same effect.

Vaccinium glauco-album is a shrub whose merits deserve a wider recognition. Though a Himalayan and not as hardy as one would wish, it is robust enough to stand at least 15° of frost. Growing to about 3ft. this vaccinium is an evergreen with hard, rough-textured ovate leaves some 2ins. long and half as wide. The stems are red, and the pinky-white flowers are borne in bold racemes, 3ins. in length, which are rendered the more attractive by the bluish-white of their conspicuous bracts. The black fruits which follow are coated by a "bloom"

Digitized by Google

of the same tint, so that the shrub both in summer and throughout the autumn is singularly pleasing.

Closely allied to vaccinium are the gaylussacias, of which G. dumosa is, perhaps, the best. People who share my partiality for ericaceous subjects will find in this species a deciduous shrub of two or more feet which adorns its downy-leaved, loose-habited branches in June with bell-shaped, pure white flowers of remarkable beauty. They will also find this huckleberry an easy and willing doer in any cool, free loam, with full exposure or part shade and one that will afford brilliant autumn tints of crimson and scarlet.

Arctostaphylos Manzanita is a most distinctive member of the ericaceæ, albeit one with which I have enjoyed a more intimate association in its own country than in this. Given a fairly sheltered position with all possible sun and not too dry a loam, the "manzanita" of California will prove reasonably hardy, while its large, heart-shaped, grey-green leaves and clusters of rose pink, white sepalled blossoms in April will always command admiration. A. Manzanita, though rarely seen, grows to about 5ft. in this country, but on its native hillsides it attains a much greater stature, sometimes forming thickets 20ft. high along the lower slopes of canons whose upper flanks are, as often as not, dappled with the dark green of the equally rare Heteromeles arbutifolia.

A. T. JOHNSON.

A NOBLE CHINESE TREE

BY E. H. WILSON.

ONE of the oldest and best known exotic trees in our gardens is Thuya orientalis, often called Biota orientalis, the Chinese Arbor-vitæ. The first mention of this tree in western literature is by Kaempfer in his "Amœnitates Exoticæ," published in 1712, where it is styled Finoke altera, with a brief description added that is sufficient for its identity. It was christened by Linnæus in 1753, but he had earlier described it in his "Hortus Cliffortianus," in 1737, where he says it was communicated by Royen and cultivated in the Botanic Gardens at Leiden. Phillip Miller had it growing in the Apothecaries Garden at Chelsea in 1752 and in the sixth edition of his dictionary, published that year, says that it had not been long in Europe and that the cones of the tree were sent from China by some of the French missionaries. Probably some Jesuit priest sent it from Peking, but I have not been able to find out anything more definite about its introduction to Europe.

Though known in Europe for nearly two centuries, I can find no record of large trees or, indeed, of specimens showing the real habit of the tree. This is all the more remarkable when its accommodating nature and ease of propagation are remembered. Dozens of forms have originated in gardens and received names, yet a real adult tree seems unknown in the entire Occident. The books devoted to conifers, even the very latest, describe it as a bush or tree of columnar or pyramidal habit, with erect branches and branchlets and from 20ft. to 60ft. high. This description faithfully portrays the tree as we of the west know it, but is far, very far from picturing its real habit.

Slow of growth it takes centuries for this tree to attain its proper form. One must go to China to see this and to Peking especially. In the grounds of the Confucian temple at Peking and in the city park near the Imperial Palace are noble arbor-vitæ trees standing isolated in groves and in avenues. These are from 70ft. to 75ft. tall and have trunks from 15ft. to 20ft. in girth, with enormous massive contorted limbs spreading horizontally and forming open, flattened-round crowns. The trunks are clothed with fibrous fissured bark, grey without and red-brown within, and some of them richly embellished with burls large and small and of fantastic shapes. Nothing could be more unlike the tree we know in western gardens than these gigantic old monarchs. Only those who have seen rugged old trees of Juniperus chinensis or of the Monterey cypress (Cupressus macrocarpa), can appreciate the astounding difference in habit between adolescence and ripe age as presented by these venerable giants in Peking.

A GIGANTIC OLD MONARCH OVER SIX HUNDRED YEARS OLD.

THE MASSIVE AND BURLED TRUNK OF THE ARBOR-VITÆ.

Digitized by Google

I have been to some pains to find out the age and history of these trees. According to the best evidence available, the Temple of Confucius was built during the Yuan dynasty and, in accordance with the custom, trees were planted at that time. The local tradition is that the trees now remaining in the main courtyard were all planted when the temple was built, with the exception of one tree, which is said to have been already there and which must, therefore, belong to the Sung dynasty. The earliest dated tablet in the temple enclosure was erected in the eleventh year of the Emperor Ta Te, *i.e.*, A.D. 1307. The Sung dynasty lasted from A.D. 970 to 1260, but was driven from Peking in 1118. The famous Emperor Kublai Khan made Peking his capital in 1264 and there the great Venetian, Marco Polo, served him as Advisory Minister. Beneath the ancient tree above referred to and others which doubtless grew with it, Marco Polo may well have rested and found shade during his sojourn at the Khan's court.

In the past many cities have occupied the present site of Peking, and as regards the trees in the city park I am informed that there is no means of determining their exact age. The evidence available would show that the oldest of them could not have been planted earlier than the reign of the Emperor Yung Lo of the Ming dynasty, A.D. 1403–25.

During my travels in the Orient I did not see spontaneous specimens of the Chinese Arbor-vitæ widely cultivated, though it is and in many places naturalised. In Korea and Japan it is known only as a planted tree. Its hardiness supports the belief that it is a native of northern China rather than of other parts of the Empire. It is the Poh-tree of the classics and the fruit, the leaves and the inner bark all have medicinal uses. In the temples the branchlets and pieces of wood are burnt as incense. In former days the tree distinguished the gardens of princes and sheltered the tombs of emperors, and to-day it is most commonly met with in gardens and burial grounds. Throughout the New Year festivities sprays of this fragrant evergreen are used to symbolise long life, happiness and prosperity.

NOTES OF THE WEEK

ATTRACTIVE EVERGREEN SHRUBS FOR PLANTING NOW.

THE introduction of the hardier escallonias, which thrive in places where the noble E. macrantha proves tender, has done a great deal to bring these fine shrubs into popularity. The hybrid named langleyensis, originating from E. macrantha and E. philippiana, is becoming increasingly appreciated, not only because of its greater endurance than E. macrantha, but because of its intrinsic beauty. It bears hosts of bright red flowers in July. The allied E. edinensis, which is understood to be of the same parentage, is even more floriferous, and, as the colour is pink, it will be acceptable as a companion to E. langleyensis. Its blooms are also a little larger. It does not seem to be generally known among amateurs that the pretty white-flowered E. philippiana is very hardy and will stand severe winters in places where E. macrantha suffers terribly in an average winter. The latter, by the way, makes a capital and beautiful seaside shrub, and by the sea is hardy even considerably north of the Tweed.—S. ARNOTT.

THE GLORIOSAS.

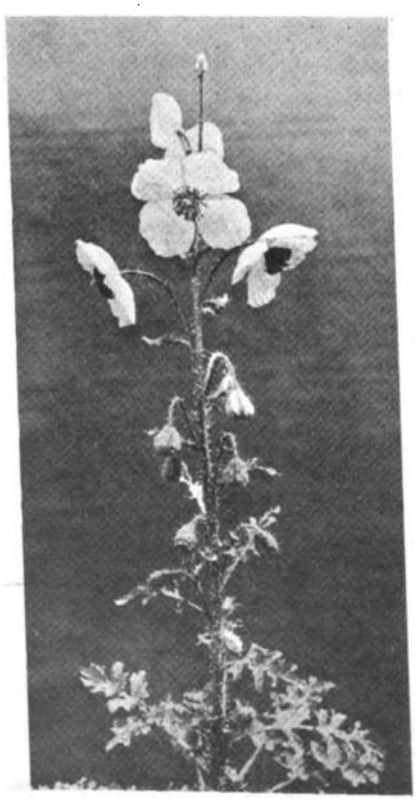
Popular Greenhouse Climbers.

THIS genus of climbers seems to be very popular among gardeners and plants of it are greatly prized. It certainly consists of very showy plants, well worthy of the little attention their growth entails. The gloriosa is a very common plant in tropical Africa, and perhaps a few notes on the conditions under which they grow naturally may suggest different methods of cultivation in this country. The situation usually given the plant in our gardens is the hottest and moistest part of the stove house, generally a position of shade. These are quite different conditions from those under which it grows naturally. It is an open grassland plant, never found in shady positions, or in the steamy atmosphere of the forest. It stands the full rigour of the tropical sun in exposed places on hill slopes, where it must often get very dry at the root; where bush fires annually burn off the dried-up vegetation, and the night temperature drops considerably below that to which the plant stove is allowed to fall. Its common associates are Clerodendron ugandensis and Pycnostachys Dawei. These latter plants are both given much cooler conditions in our plant houses, and there seems to be no reason why gloriosas should not succeed with them.

I agree that gloriosas are very well grown in our gardens, but I imagine that the flowers would be much more highly coloured, and more freely produced, were natural conditions more faithfully copied. Moreover, doubtless many gardeners have hesitated to attempt their cultivation, under the belief that extreme heat is a necessity. Naturally, the tubers are deeply buried—at least 18ins.—and for this reason it is quite difficult to eradicate the plant when clearing land for plantation purposes.—E. BROWN, *Kent*.

ANOTHER BLUE POPPY.

THE enclosed photograph shows Meconopsis aculeata, which flowered in my garden in Perthshire last summer. This is one of



THE SKY BLUE MECONOPSIS ACULEATA

the biennial species and grows about 18ins. high. The flowers are normally a sky blue colour, but some of the seedlings had flowers of a reddish and purple colour. The foliage is quite distinct from that of the other blue meconopsis, such as latifolia and Prattii, as can be seen from the illustration. It is much more cut or fern-like. M. aculeata sets seed freely and is easily raised, and well worth the attention of gardeners who grow a selection of these poppies.—A. HARLEY.

A VALUABLE TROPHY FOR PLANT BREEDERS.

A HAPPY thought inspired Messrs. Abol, Limited, when they decided to recognise in a handsome and generous manner the important and valuable achievements of our plant breeders. The "Abol" Challenge Trophy, value seventy guineas, is to be offered at the Staffordshire and Midland Counties Show, to be held on August 11th and 12th at Burton-on-Trent, for the exhibit which demonstrates the greatest development or improvement of recent years in any one family, strain or variety of plants or their produce. It is a noble gift for a worthy purpose. The term "recent years" may be broadly interpreted to mean since the war, but, wisely, it does not sharply cut a dividing line on the basis of dates, the sole desire being to bring together for comparison all the new breaks, strains, selections and hybrids which have carried British horticulture far along the road of progress, and to select for the highest honour that particular subject which is considered to mark the greatest stride of improvement upon the types or kinds from which it was produced. Truly, this should create a class of unbounded interest, and focus the attention of all sections of the horticultural world upon the outcome of the plodding labours of our hybridists and plant breeders.

There are points in this novel idea which command particular attention, and upon which comment may well be made. It would be obviously impossible at any one show to bring the plants and flowers of all seasons into the arena, but Messrs. Abol's choice of an August show ensures a "lead off" at the period of greatest abundance in floral treasures. The venue, too, has been well chosen. Burton-on-Trent is very centrally situated: it is accessible alike to northern, southern, eastern and western exhibitors, and the show attracts an immense throng of visitors. The show is young, but wonderfully well planned and managed, and its future is full of promise. It is understood that in fairness to all sections of horticulture the trophy will in due time be offered at spring shows and autumn shows, and in various centres. The winner each year will receive a permanent memento of his success, and the name of each holder of the trophy will be engraved upon it.

It would be invidious to say in advance of the show to what subject it should be given, but one may quite appropriately mention various things that ought to be

Digitized by Google

well represented in the class. Southern growers will find it late to show their finest delphiniums at the top of their form, and it would undoubtedly require the very best to mark the real extent of recent progress, for it must be admitted we had extremely fine delphiniums some years previously to the war. There are northern specialists, however, who will probably be in quite good form about that period of August. We have various strains of perpetual border carnations and perpetual pinks which are decidedly of modern development, and the "House" race of selected varieties of Scabiosa caucasica affords a striking instance of modern development in a most serviceable flower. This trophy class should afford an excellent opportunity to compare and place a decisive estimate upon the relative value of the numerous distinct classes of lupins which certainly have made somewhat sensational strides of progress in recent years, and it may well be found that some wonderful astilbes, of which remarkable developments have been seen in certain quarters, will come forward in grand form.

What may be seen in annual flowers it is difficult to foretell, but, of course, many of to-day's most meritorious strains and stocks of annuals have been the result of long years of patient and painstaking selection rather than the outcome of startling new breaks of hitherto unknown character. Possibly, in greenhouse plants, the new bi-generic hybrids between achimenes and gesneras may challenge the hardy flowers for prior claim to honour, and in hydrangeas we may see a demonstration of very pronounced advancement.

Gladioli of the primulinus hybrid class are practically certain to make a bold bid for distinction, more especially as the same show is the venue of the gladiolus exhibition.

Truly, there is no dearth of material for the making of a glorious display to the great honour of British horticulture.—A. J. MACSELF.

RANUNCULUS AMPLEXICAULIS.

SOME of the alpine gems of the genus ranunculus are troublesome things in the ordinary border and require to be relegated to some specially favoured spot in the rock garden, where their idiosyncrasies can be humoured. Ranunculus amplexicaulis, on the contrary, though it is not of

CASSIOPE SELAGINOIDES, A NEW AND ATTRACTIVE REPRESENTATIVE OF THE HEATH FAMILY.

miniature growth and is less suitable for the rock garden than the border, is very easy and gives one practically no trouble, while in the garden in summer it is not only pleasing but distinct from many of its neighbours. A rich soil is recommended with wisdom, but all do not possess a garden of rich loam, and R. amplexicaulis does not resent a poorer fare, and the writer grew good plants for years in a sandy soil with a poor, dry subsoil of sand below. There the plants throve, though not with the same robustness as they attained in the soil of the fertile garden whence they originally came. Yet they were happy and beautiful.

R. amplexicaulis is a distinct-looking plant, growing from about 9ins. to 1ft. high, and having rather large, oval pointed leaves of glaucous blue-green, which clasp round the stems, giving origin to the specific name of amplexicaulis, or stem-clasping. These stems are surmounted by large, broad-petalled flowers of a pure white, forming, altogether, a very distinct summer-flowering subject. Any ordinary border will do for R. amplexicaulis, and it can be grown well in sun or partial shade. Propagation is effected by division, preferably in spring.—DUMFRIES.

AN ALPINE FOR EVERY GARDEN.

A VALUABLE little alpine plant, easy to grow in almost every garden, and giving for a good length of time in summer its flat heads of yellow flowers above woolly-looking foliage of considerable charm. Such is Achillea tomentosa, a lover of dry and sunny places from far-off lands, such as Siberia, which has been in our gardens for many years. It soon makes a good clump when happy, and is effective with its gay heads of yellow flowers 6ins. or 9ins. above the flat carpet of foliage. It loves, as mentioned above, a dry place and a sunny bank or the warmest slopes of the rock garden will suit it well. A very pretty plant of the same character, generally called A. King Edward, has been in commerce for some time. It has pale yellow flowers and is much admired by growers of alpine plants. A. tomentosa is increased by seeds, division and cuttings, and A. King Edward by division or cuttings. These good plants may be planted any time.—S. ARNOTT.

CASSIOPE SELAGINOIDES.

A Valuable Rock Garden Plant.

THIS is a most beautiful plant, and, should it prove to be hardy, will be a great asset to the rock garden. It has a fine habit and forms a close, compact mass of growth. The seed of this plant was gifted to the Royal Botanic Garden, Edinburgh, on April 19th, 1922, by Mr. Reginald Cory. The plants are now well established. There are, however, two forms of this plant, one plant having a green tomentose pedicel and green calyx—the same as Fig. B. 9003, *Bot. Mag.*; whereas the other plant has a reddish brown hairy pedicel with a calyx the same colour. The plant with the reddish brown pedicel and calyx is the more showy, but the two forms seem to have equal vigour. The plants have now attained a height of 3ins.; the pedicels are 1–1¼ins. in length and throw the flowers well above the growth, which helps them to be seen at a distance. The flower tubes measure ⅜in. at the mouth of the bell. Regarding the cultivation of this plant, it will be found that the grower can handle it with impunity, as the plants growing in this garden have been shaken out, repotted in small pots, and none seemed to mind the treatment; whereas in the spp. C. fastigiata and C. tetragona they are both very impatient at being disturbed at the root. They can all be propagated by seeds or by cuttings, but the establishment of C. selaginoides is by far the more easy. The plant at this season is one mass of bloom and should soon become a popular garden plant.—L. B. S.

AN INTERESTING TENDER SHRUB.

IN gardening, the unexpected always seems to be turning up and it came as no surprise to me, while walking round a garden in Cornwall a few weeks ago, to stumble across that tender Australian shrub, Correa speciosa,

CORREA SPECIOSA GROWING OUTSIDE.

growing happily out of doors. There was no appearance of home sickness about it or even a suggestion that it was longing for the barren stretches of sandy waste of its native home. It apparently had taken kindly to its new quarters, where, by the way, is housed probably the finest collection of Australian and New Zealand shrubs outside a botanic garden.

Cornwall is a county where the majority of things grow moderately well and those who are lucky enough to garden in that corner of the country can try their hand at growing many plants out of doors which by others less favourably situated must be grown inside. C. speciosa is a shrub, I should imagine, which will do fairly well on the west coast, even far north if it is given a sheltered situation. In the garden I have in mind it was growing on the edge of a raised bed under the shelter of two lofty Pinus insignis and numerous other taller growing but tender shrubs. The garden stands moderately high and in addition has to withstand the full blast of a south-west wind, which, judging from my experience of a few days, is of great severity.

It forms a striking little shrub some 2ft. to 3ft. high, with slender, brownish branches, which are loose and rather spreading. The foliage is attractive, small and neat, with a dark green upper surface and a felted white reverse. It is when in flower, however, that the shrub becomes of real beauty. The long, almost bright scarlet tubular flowers are borne with a free will and hang gracefully from the slender shoots on dangling stalks, giving the bush a well furnished appearance.

In less favoured situations it is a plant which is well worth growing in a greenhouse, both for the sake of its ornamental flowers and its decorative foliage.—G. T.

AQUATICS FOR PRESENT PLANTING

IT is at this season of the year when all water plants and ponds should be thoroughly overhauled in preparation for the summer and autumn. In close proximity to the rock garden are often found pools of various shapes and sizes where water lilies and other aquatic plants find a congenial home. It should be clearly understood that a rock garden is not a necessity to water gardening, and it should be borne in mind that the nymphæas and other plants mentioned in this article are quite hardy. Splendid results can be obtained in small ponds and shallow lakes, tanks, gentle streams, moats, etc., whether artificial or not. An ample water supply is essential, and an efficient outlet to prevent stagnation. Ordinary barrels cut across the middle are often employed for water lilies, and, if needed, the tubs could be sunk to the ground level. A well arranged collection of aquatics will soon beautify an otherwise uninteresting piece of water. A barren, boggy piece of land where little but foul water and coarse rushes exist could often be made beautiful by cutting a few channels and the judicious use of drain-pipes, so guiding the water into one large pond or a series of small pools. These would suit the water lilies, and the margins could be filled with a host of other subjects, which must be dealt with in another note. For the present I confine my remarks to plants that will succeed in water. The nymphæas, of course, will make the principal feature, and the less rampant species and hybrids will need a depth of about 18ins. of water; while the stronger growing kinds, such as N. Marliacea chromatella, should be placed in water to a depth of 2ft. These figures are for small pools or tanks; but for larger areas the more robust lilies will succeed at a depth of 4ft.

THE STATELY BLOSSOMS AND HANDSOME FOLIAGE OF N. STELLATA.

In time the crowns become overcrowded, and it is then advisable to divide them. The best time to do this, and to plant out new varieties or make fresh colonies is from early April to the beginning of June.

Overcrowding, especially in small areas, must be avoided, or many of the flowers will never be seen, while the leaves will rise above the water considerably and much of the beauty will be lost. A few of the leaves may be cut out, but it is a practice to be condemned if carried out on a large scale. It is much better to run off the water about the end of March and remove the small crowns, which usually produce foliage only. These, if taken off, with a little care will readily establish themselves in new positions where they have ample space to develop. At the bottom of the pool will be found a layer of what is commonly referred to as "mud," but this should be left, as it will form a rooting medium for the lilies. The planting of nymphæas is a comparatively easy task. Old wicker baskets about 2ft. across are obtained and the roots placed in these, filling up the intervening spaces with good fibrous loam. Pieces of wire netting will be found useful if bent round in a way similar to a basket. When the planting is completed, make the soil secure with strong string. Now the whole will be ready for its final quarters, and the operation is finished by dropping the plants wherever desired.

If there is a tendency for the baskets to "float," a few stones will be sufficient to keep them in position. Where a start is made with good plants, there is rarely a failure; growth will soon commence, and a number of flowers will appear the first season. The nymphæas constitute a charming and varied group of aquatics, and if a judicious selection is made the pools or streams will be a leading feature of the garden throughout the summer and autumn months. One of the best hardiest yellows is N. Marliacea chromatella; it is a strong grower, and well adapted to large areas where there is a depth of 2ft. to 4ft. of water. N. M. rosea is a pink or soft rose; while N. M. albida is white. Another good white is N. Gladstoniana, and one of the darkest-coloured lilies is N. William Falconer, but not free flowering. Other desirable varieties are N. W. B. Shaw, bright rosy pink; N. Robinsoni, orange red; N. odorata, pure white; N. o. rosea, rose pink; N. o. gigantea, white; the new Escarboucle, deep vermilion red; and N. odorata exquisite, a beautiful deep rose carmine in colour. For shallow water such as tanks, tubs or basins, the most suitable embrace the following varieties: N. Laydekeri rosea, soft rose pink; N. pygmæa, white; N. p. Helvola, yellow; N. odorata minor, white; and N. Seignoureti, yellow shaded carmine and pink. For very large areas our old favourite English water lily, N. alba, should be included, but bear in mind it is a quick grower.

Stagnant water is not suitable for water lilies, neither is a fast-running stream; to prevent the former, the water should be changed occasionally; and the latter is a failure because the soil would be washed away from the

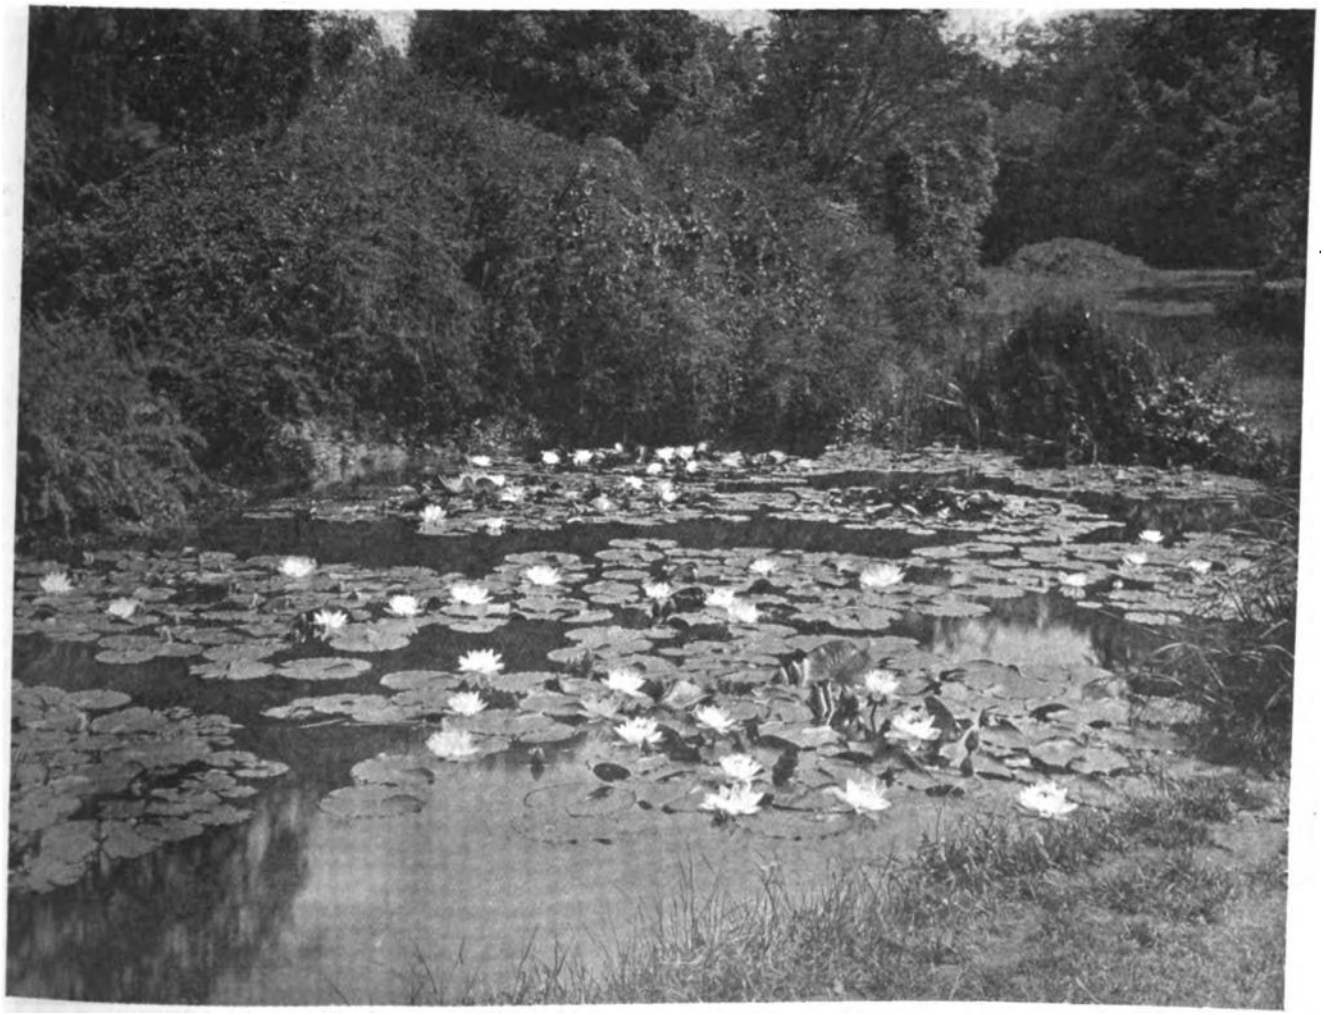
Digitized by Google

roots. Few insect pests trouble nymphæas, but occasionally, during a spell of hot weather the black aphides will appear on the leaves. The hose-pipe with a good pressure of water will remove these marauders if employed daily for about a week. If any fungoid disease is present on the foliage, a weak solution of Bordeaux mixture sprayed over the leaves will soon cure it. This operation should be carried out every second day for a week, and late in the afternoon is the safest time for spraying. Leaves badly affected must be collected and burnt.

A number of other plants could be grown in water, such as the fragrant sweet "flowering hawthorn," Aponogeton distachyon. Its white flowers float on the water in pairs. The typha family, such as T. angustifolia and T. latifolia, "Common Cat's-tail," produce a fine effect in a large piece of water where there is ample space for development. Their spathes on 6ft. to 9ft. stems are quite a feature in the autumn months. For a shallow spot, too, we have the bog bean, Menyanthes trifoliata, whose bean-shaped leaves and pale pink flowers are always full of interest. Stratiotes aloides, the "water soldier," produces white flowers on stems 6ins. or so in length. The arrow-heads, Sagittaria sagittifolia, and S. gracilis, are useful; also the water violet, Hottonia palustris; Villarsia Nymphoides, a quick growing little plant with yellow flowers; Caltha palustris, the marsh marigold, is a quaint yet pretty plant; while the water buttercup, Ranunculus lingua, grows about 2ft. high and produces a quantity of large golden yellow flowers. The white R. aquatilis, on the other hand, keeps to the water's surface, which is studded with numerous white flowers with yellow stamens.

THE OLD-FASHIONED MARSH MARIGOLD IS MOST EFFECTIVE AT THE POND SIDE.

There are other subjects suitable for our purpose, but sufficient have been mentioned to create an interest in this delightful branch of gardening, and to show what a wealth of material there is to choose from. T. W. BRISCOE.



AN IDEAL HOME FOR THE BEAUTY OF THE WATER LILY IN THE QUIET OF A WOODLAND POOL. THE WAXEN WHITE FLOWERS STAND OUT LIKE MAMMOTH STARS FROM THE MASSIVE FOLIAGE.

GREENHOUSE CARNATIONS AT WESTMINSTER

THE decorative value of the greenhouse carnation was well illustrated on the occasion of the Spring Show of the British Carnation Society, which was held at the Royal Horticultural Society's Hall, Westminster, on April 15th last. In the middle of the hall there were some very effective dinner-table decorations, and the first prize "confection" of Mrs. A. Swann, Colwood Lodge, Warninglid, Hayward's Heath, was particularly charming. Mr. R. H. Hall, Hatfield House Gardens, was second, with a good pink carnation, probably Laddie.

The four exhibits of not more than 100 carnation blooms arranged on a table space were also highly decorative. The first prize display of Mr. E. Martin Smith, Codicote Lodge, Welwyn, Herts, was an excellent example of splendidly grown blooms arranged with artistic skill. Sir Randolf Baker, Bt., Ranston, Blandford, who was second, had, in the centre, a pretty raised basket of Laddie, with surrounding vases of Spectrum, Topsy, Crystal White and Saffron. This, also, was an exhibit of considerable excellence.

There was only one collection of carnation plants, and this was a magnificent group sent by Sir Charles Nall-Cain, Bt., Brocket Hall, Hatfield. The many plants were perfect examples of such sorts as Laddie, Saffron, Topsy, Carola and Lady Northcliffe, and they were skilfully arranged.

In the open classes, the tall vases of 100 blooms each were placed at intervals in the middle of the staging, where, rising above the other exhibits, they made a delightful display. The rules seem to permit a competitor to show as many exhibits in a class as he wishes, though only one prize may be taken, and in this class Mr. C. Engelmann had several magnificent vases. That of the rich salmon pink Laddie won the first prize; while Mrs. Walter Burns, North Mimms Park, Hatfield, was second with another good pink variety. Mr. Engelmann was the only exhibitor of seven vases of twenty-five blooms each, and he was awarded the Monro Silver-gilt Challenge Cup for splendid blooms of Laddie, Cupid and Improved Ward, of pink shades, White Enchantress and the fragrant Mary Allwood.

The best three vases of English-raised novelties were of Carola Striata, crimson with scarlet flakes; Janet, cerise; and Dainty; while the chief American novelties were Spectrum, scarlet; Surprise, salmon pink; and Donald, crimson. Both first prizes were won by Mr. Engelmann. He also had the best large vase of a British novelty, where he showed Katja, a very large dusky heliotrope flower; and was first with Dorcas, a delicious bloom, as the most fragrant crimson variety.

To test the lasting properties of the varieties, the Society has an interesting competition. A box of twenty-four blooms of one variety has to be posted three clear days before the Show. They are opened at 5 p.m. on the day before the Show, placed in water, and judged on the morning of the Show. Eight boxes were sent, and the prize was awarded to magnificent blooms of the rich pink Laddie, sent by Mr. Engelmann, which seemed as fresh as though they had just been gathered. The other sorts sent in competition included Starter, Lady Northcliffe and Wivelsfield Apricot, and all of them stood the trying condition very well indeed. Also of great value and interest was the class for two boxes of distinct varieties as packed for market. This also was very popular with the trade growers, and the judges had no enviable task, for all were splendidly packed. The first prize was awarded to Messrs. Allwood Brothers, whose varieties were Wivelsfield Apricot and the blush salmon George Allwood. Mr. W. H. Page was second, and Mr. C. Engelmann was third.

What may be termed the Colour classes were very instructive, as they enabled visitors easily to select the best variety of all of the different colours. The first prize-winning varieties were White Pearl; Master Michael Stoop, in the light rose or deep pink class; Laddie, salmon pink; Tarzan, red; Topsy, crimson; Mrs. Hamilton Fellowes, purple; and Saffron, yellow. The best fancy carnation was the blush mauve Chintz, with the striped Benora second. Miss M. Pixley, Wooburn House, Wooburn Green, Bucks, had the best salmon pink blooms; and the other first prizes were won by Mr. C. Engelmann and Messrs. Allwood Brothers. Then, as though to show how beautiful the selected varieties are when tastefully arranged together in a large vase, there was a class for a bloom each of the twelve colour classes of the Society, and here Messrs. Allwood Brothers were first, and Mr. C. Engelmann, who had the best vase of apricot shades, was second.

In the amateurs' classes the same high quality was continued. Lady Mond, D.B.E., Melchet Court, Romsey, was first in the British-raised novelty class, with magnificent blooms of Melchet Beauty, of beautiful heliotrope colour flaked with scarlet, and other sorts. Mrs. Walter Hyde, Kempton House, Sunbury, won the Stuart Low and Co.'s prize, with an admirable collection; and Mr. S. T. Hore, Wonham Hill, Betchworth, was first with a decorative vase of carnations.

In the colour classes of this section the best varieties were Crystal White, R. F. Felton, light rose; Baroness de Brienen, salmon pink; Tarzan, red; Topsy, crimson; Saffron, yellow; Mary Pearson, heliotrope; and Jona, fancy. Especially good vases were shown by Lady Mond, Sir Charles Nall-Cain, Bt., Sir Randolf Baker, Bt., Mrs. E. Martin Smith and Mr. S. T. Hore, in these classes. In this section there was also a class for a large vase of the different sorts taken from the colour classes, and Sir Randolf Baker was first with a splendid exhibit.

Four classes were provided for members who are unable personally to attend the Show, and their exhibits are staged by the Society. Mr. John Hanmer, Pinewood Towers, Conway, won one of the first prizes; and Mr. Ernest Walker, Radcliffe-on-Trent, won the others. Both sent highly creditable blooms. Mrs. Walter Hyde, Kempton Park, Sunbury, was similarly first with a very good vase of twelve blooms in not fewer than four varieties; and Mr. R. H. Hall, The Gardens, Hatfield House, Hatfield, had the best decorative bowl of carnations.

THE DAFFODIL SHOW

EXCEPT for some, relatively few, spaces, reserved for exhibits in the amateurs' division, which did not materialise, the Royal Horticultural Hall at Westminster was filled with a wonderful array of daffodils and narcissi on the occasion of the annual Daffodil Show of the Society, on April 13th and 14th.

All around the Hall there were the generous collections of all the noted trade growers and some of the amateurs who specialise in narcissi. Near the clock, Mr. P. D. Williams, Lanarth, St. Keverne, Cornwall, set out a choice selection of his famous seedlings. Many of them still had their seedling numbers, they were, of course, some of the newest and best of the Lanarth raising and destined to have distinctive names in the near future. Of those already named, St. Anthony, a vividly coloured Barrii; St. Glavias, a twin poetaz variety with flowers as large as those of Barrii type; Gulliver, with a deep primrose perianth and fiery orange corona; and Kynance, which has a white perianth and an orange cup, were beautiful examples.

Mr. W. B. Cranfield, another well known amateur raiser, had a charming selection of his new narcissi of various types and also set up beautiful vases of Venetia, Wistful and St. Olaf, three chaste Leedsii varieties. But the variety of the Show was Firetail, which he and others showed so well and, considering its relative newness, in quantity. It was the best of all the many Barrii narcissi with vividly coloured coronas which is set off by a smooth, overlapping primrose coloured perianth. The specialists say that it increases rapidly, so, soon, the price will permit extensive planting, when it will have a great future, both as a garden flower and for house decoration.

Firetail was also shown splendidly by the Donard Nursery Co. in their extensive collection of most desirable varieties. Moira O'Neill, a bicolor trumpet daffodil with a perfectly formed, clear lemon tube; White Wax, of similar type, but with a paler trumpet; Festive and Tempest, incomparabilis with orange coloured crowns; Vintage, a white trumpet; Spanish Flag, which has a very large flattened crown with uncommon alternations of orange and yellow; Gallipoli one of the best of the giant incomparabilis; and Herod, a handsome bicolor trumpet, are the names of only a few of their magnificent sorts.

Although it is full early for the poet's narcissus, Messrs. Barr and Sons had quite a number of beautiful varieties in their excellent exhibit, and these were all of the best type, which has a small, brightly coloured corona in a perfectly round perianth of sparkling waxy whiteness. Juliet, Horace, Kestral, Oracle, James Hogg, and Nightingale, were the best examples. But fascinating as these were it was to the centre vases of Mrs. R. O. Backhouse that every eye returned. At present this wonderful narcissus, with its long pink tube, is the rich man's flower, but later on everyone will be ordering it. Prince of Wales, a rich yellow trumpet daffodil; Washington, incomparabilis with an immense yellow cup; Gertie Miller, a giant Leedsii, with widely expanded primrose tube; Virgilia, of similar type, with lemon yellow tube; and Diana Kasner, which has an orange tipped corona and white perianth, were all very fascinating.

The Barrii sorts made a bright display in the excellent exhibit of Messrs. J. R. Pearson and Sons, who gave special prominence to Firetail, Marshlight, Joan of Arc and Miss Bartley, which has a glowing crimson crown. Crœsus, Gertie Miller and Countess of Radnor, were noteworthy incomparabilis sorts, while John Cairns, a fine trumpet, also attracted much admiration. Mr. Guy Wilson had vases of Bulwark and Goldbeater, rich yellow trumpets; Beersheba, white trumpet; Rose Morran Giant, bicolor trumpet; and Hymethus, a widely opened trumpet tipped with lemon yellow. Fair Lady, Noel, Joan of Arc and Matthew Arnold, poeticus; Buttercup, of rich colour; Phyllidia, large incomparabilis; and several of the fragrant poetaz varieties were well shown by Messrs. R. H. Bath, Limited.

Many of the best sorts and various seedlings were shown by Mr. J. W. Barr, who had some charming small Leedsii varieties; and the Welsh Bulb Fields Co., who included Twinkle (a delightful little flower of apricot flushing).

Digitized by Google

Jingle (a vivid Barrii) and Phyllis Vansittart. Mr. J. L. Richardson had many good trumpet daffodils, including Lady Primrose, White Knight, Mrs. Wakefield, Christie Miller and Master Robert.

Seedlings of merit were shown by Messrs. Cartwright and Goodwin and Mr. W. F. M. Copeland, who had pretty Leedsii and other varieties; and Messrs. Dobbie and Co. set out a quantity of the Leedsii variety, Osprey, very attractively in mounds of moss.

Of quite distinctive character was the exhibit of Messrs. Seymour Cobley, Limited, who grow at Spalding countless numbers of English raised daffodil bulbs for marketing. They had panels of market bunches of the highest quality, which made a striking show. The chief varieties were white Lady Leedsii; Firetail, in astonishing quantity; Crœsus, incomparabilis, with orange corona; Robespierre, Barrii, and an excellent seedling poet's narcissus.

COMPETITIVE CLASSES.

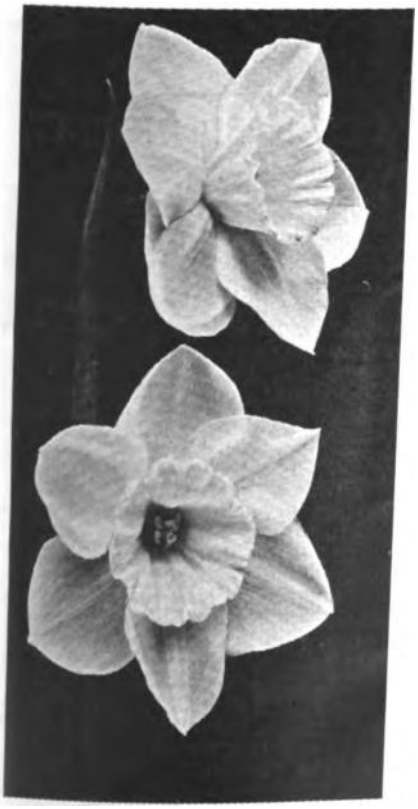
Except, as we have remarked, for some in the amateur division, the classes were well filled, though in nearly every section the same names appeared on the prize-winning tickets. Mr. P. D. Williams was first and Mr. J. L. Richardson was second in the class for twelve varieties of any division of narcissus, but unfortunately the very best of their splendid exhibits were unnamed seedlings.

In the class for twelve varieties of the different types, the Donard Nursery Co., Mr. Guy Wilson and Mr. J. L. Richardson, were the principal first prize winners. The competition among them was very keen and in the class for poet's narcissus the judges could not discriminate between Mr. Richardson and Mr. F. H. Chapman, so placed them equal first. In respect to equal firsts the show must constitute a record, for this happened in three of the classes.

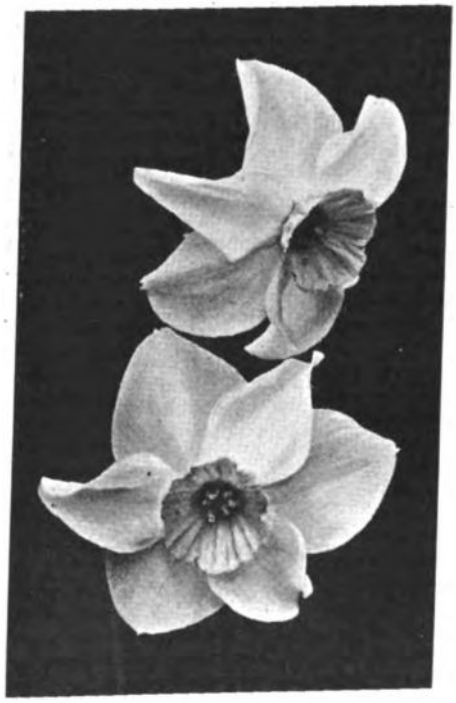
Although the classes for new varieties raised by the exhibitor did not bring many competitors, there were some lovely flowers to be seen. Mr. P. D. Williams was first in the large class, where he showed Folly and Traboe, which both received awards of merit, and Menadue, a perfectly formed poeticus variety with a small orange scarlet corona. The next class was won by Mr. E. T. England of Baring Place, Exeter, and the Rev. T. Buncombe, Black Torrington, North Devon, was first with three varieties; both had unnamed seedlings.

The class for twelve varieties was fairly well filled, but the first prize did not seem to be awarded. The Rev. H. Rollo Meyer, Watton Rectory, Hertford, had the best six varieties and his were unnamed, while Mr. England, who had a lovely vase of Monitor, a bicolor trumpet, was first with three varieties.

There were sixteen classes each for a single bloom of the different divisions. The principal first prize winners were Mr. W. B. Cranfield, Mr. J. L. Richardson, The Donard Nursery Co., Mr. W. F. M. Copeland. These classes lost much of their value to the visitor in that several of the first prize winning blooms were unnamed.



WHITE SENTINEL, A GIANT LEEDSII OF GOOD SUBSTANCE.



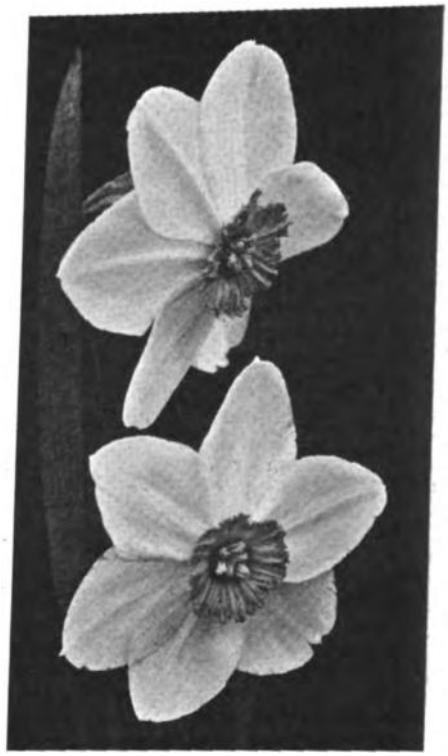
FOLLY, A NEW INCOMPARABILIS VARIETY.

The best amateur's collection was set up by Mr. W. B. Cranfield, East Lodge, Enfield Chase, whose twenty-four varieties were of high merit. Mr. Cranfield also won most of the other first prizes in the section and also the Barr Silver Vase. The fine array of novices' classes was disappointing, for there were few exhibitors. Mr. H. J. Morris, Woodfield House, Penryn, was the chief exhibitor and he was awarded many first and second prizes for praiseworthy exhibits.

NEW DAFFODILS.

A first class certificate was awarded to "Red Rim," and awards of merit to the remainder of the following varieties:

RED RIM.—A very shapely poeticus variety with a round white perianth and a flat corona of greenish yellow colour with a distinct fiery orange margin. Shown by Mr. F. A. Secrett.



NARCISSUS MULBERRY, A BEAUTIFUL BARRII, WITH A GLOWING ORANGE CUP

BETHA.—Two vases of this very fragrant poetaz variety were shown, one contained single blooms on a stem and the other was of twin-flowered blooms. The blooms are round and approach in size those of a Barrii variety. They have a primrose-coloured perianth and corona of the same colour, with a narrow, deep orange rim. Shown by Mr. W. Welshman.

CARMEL.—A large bicolor trumpet daffodil. It has a white perianth and a long, lemon-coloured tube with an attractively waved margin. Shown by Mr. Guy Wilson.

FOLLY.—A large incomparabilis variety with a white perianth and a basin-shaped, fiery orange corona. Shown by Mr. P. D. Williams.

MULBERRY.—A beautiful Barrii variety which has a white perianth and a flattened, fluted corona of rich orange colour, shading to a deeper tone at the margin. Shown by Mr. P. D. Williams.

PAPYRUS.—A very valuable poeticus variety, which has a substantial round white perianth and a slightly cupped corona with a fiery orange rim. Shown by Mr. F. A. Secrett.

SAMARIA.—A beautifully formed Leedsii variety with a white perianth as substantial and round as any of the best Poeticus type. The small white corona is prettily frilled and has a pale yellow rim. Shown by Mr. F. Herbert Chapman.

SERAGLIO.—A large Barrii variety with a pale primrose perianth and a yellow basin-shaped corona with a deep orange rim. Shown by Mr. J. L. Richardson.

TRABOE.—A striking Barrii variety with a corona which is green in the centre, yellow midway and rich orange scarlet at the margin. Shown by Mr. P. D. Williams.

VALETTA.—A handsome white trumpet variety. The wide tube is attractively frilled. Shown by Mr. Guy Wilson.

WHITE SENTINEL.—A giant Leedsii variety with a short, funnel-shaped cup of pale primrose colour. Shown by Mr. J. L. Richardson.

MOWING MACHINES AND THEIR SELECTION

IN THIS ARTICLE IS DESCRIBED A NUMBER OF SUITABLE HAND-DRIVEN MACHINES, ANY ONE OF WHICH WILL PROVE SERVICEABLE IN THE ORDINARY-SIZED GARDEN.

THE purchase of a mowing machine is not a task in which many of us can afford to indulge every year, and, as it is an implement which usually comes in for a fair share of hard work each season, it is as well to exercise a little care in the selection of a suitable machine which can be depended upon to give the maximum amount of efficient service. There are so many different makes on the market to-day that a very wide choice is offered. Unfortunately, a number of them are constructed of such poor materials and badly finished parts that it is wise to hesitate before purchasing in this direction, though the low price quoted often forms a tempting bait. A reliable machine should give practically a lifetime's service, provided it receives proper treatment and careful attention. On the other hand, a poor machine is just as likely to be a source of constant trouble, no matter how carefully it is looked after. When thinking of lawn mowers the names of several reputable firms who specialise in their manufacture automatically come to one's mind, and it is as well when examining a probable purchase to look for the maker's name. That which has no name seldom has much reputation; while a machine bearing the name of a specialist maker carries with it a reputation gained by many years of careful study and experience. The actual selection of a suitable machine will, of course, be governed by individual circumstances and requirements, but the main points to be looked for are practically the same, whether it be a small machine with only an 8in. cut or one of the larger types with a cut of anything up to 30ins. It will be found that the side wheel machine is the easier to push, but the roller machine gives a much better finish at the expense of slightly more energy, and, for general all-round efficiency, would always be my selection. The latter type can be obtained with either gear or chain drive from the land roller to the cutting cylinder. Of the two, I prefer the chain drive, which, in spite of the necessity for occasional adjustments, is usually very much easier to push. Many of the later types of machine are fitted with ball bearings, a factor which lends itself to easy working. Make sure that the arrangements for adjustment of both cutters and front roller are of the simplest possible nature and easily accessible, and also that lubrication is allowed for at every bearing. Another excellent point embodied in many machines are adjustable handles, which, by simply loosening two nuts, can be arranged to suit the height and likes of any individual user. It will usually be found that a 14in. machine is quite large and heavy enough for one man to work by himself, and this factor should be taken into consideration where it is not desirable to employ additional labour. Having secured a sound machine, particular attention should be paid to its upkeep in after use if the best service is required from it. More damage can be done in a few weeks by faulty adjustments, careless usage, etc., than by years of hard work. No machine should ever be put away after use until it has been cleaned. This, if done regularly, is an operation which takes but a few moments to perform. An old spoke brush will be found to remove most of the dirt and mowings picked up during use; while a disused tooth brush, or even a piece of thin wood, will serve to reach the more inaccessible parts of the mechanism. Having removed the dirt and other foreign matter, wipe all parts, especially the cutting blades, with a greasy rag. Oil the machine regularly during use, and the benefit will be found in ease of working. Use a good oil which is neither too heavy nor too thin, and do not scatter it broadcast over the machine. Oil only at the correct lubricating points on each bearing, and this should be found quite sufficient. When the cutting cylinders become dull and blunt through hard wear, it is not advisable to attempt to sharpen them with the aid of a grindstone or file. Very few amateurs are sufficiently skilful to tackle this operation successfully. To sharpen cutters of this description in a proper manner involves the use of an elaborate plant, and in most towns of any importance there are workshops specially equipped for dealing with this at a trifling cost. Most manufacturers have a repair service department, and if the machine is sent direct to them when sharpening is required, the sender can rest assured that it will be thoroughly overhauled before it is returned. A few brief particulars are appended herewith which will provide readers with a comprehensive selection of reliable and trustworthy machines. Among the hand machines made by Messrs. Thomas Green and Sons, the *Model de Luxe* "Silens Messor" deserves special mention. Its cutting cylinder is equipped with nine blades, and an easy free-wheel action is incorporated. It is easily adjusted, being fitted with self-aligning ball bearings. The aluminium chain-gear-case forms an oil bath, and special provision has been made for lubrication in all parts. It is made in 12in., 14in. and 16in. sizes. The firm of Ransomes, Sims and Jefferies publishes a list containing many different types of machine; but for the purpose of this article special mention need only be made of two of the most popular makes, *viz.*, the "Marquis" and the "Automaton." The main features of the former are: Self-aligning ball bearings to every journal, in dust-proof housings; enclosed roller chain, which is grease-lubricated; no open oil holes; simple screw adjustments to cutting cylinder and front rollers; and adjustable handles to suit user. The "Automaton" is made in all sizes from 8in. to 24in., and is fitted with either gear or chain drive. They are fitted with ribbed rollers and a drawing rope and handle is supplied with all machines from 14in. upwards. The models of Messrs. Alex. Shanks and Son include the well known "Talisman" and "Standard" machines. The first-named are of the side wheel type and are easy running and clean cutting in use. They are made in all sizes. The latter type can be obtained with either chain or gear drive, and are fitted with double-edged sole plate and reversible cutters. In each case the handles are adjustable to suit the user. Special machines can be obtained fitted with ball bearings.

The "J P. Super Lawn Mower" has been described as the "Rolls Royce" of mowers, and its manufacture certainly leaves little to be desired. All parts, including the rotary cutters, are interchangeable and run on ball bearings, while the gears, etc., are encased in aluminium dust-proof covers and run in oil. The land roller is in three sections, which prevents the turf from being torn while turning. Adjustment is very simply arranged by the manipulation of two small hand wheels, and it is a machine which can be relied upon to give excellent service in every way.

The "Pennsylvania" is a side wheel machine made in various sizes, with either high or low side wheels. It is intended for hard wear, and in actual use is very easy running. There is a machine of this type for practically every use, from cutting a small grass border to mowing the fairway of a golf course, and all machines are fitted with oil-hardened and water-tempered cutters. In all the machines mentioned parts are interchangeable and can easily be procured if new ones become necessary.

A. J. C.

(*To be continued.*)

CORRESPONDENCE

TROPÆOLUM SPECIOSUM.

SIR,—I am interested in Mr. Comber's remarks on Tropæolum speciosum. Here we are sixteen miles from Bath, five miles from Wells, 550ft. above sea level, annual average rainfall 46.55ins.

We have T. speciosum planted on the north-east side of a holly hedge; it comes over the top and through the hedge, and flowered magnificently last year. It also flowers luxuriantly in another part of the garden, climbing over rhododendrons.—WALDEGRAVE.

A WINTER GARDEN.

SIR,—Will it interest any of your readers who are beginning to make and enjoy a garden to hear about an outdoor garden during the past three months? Many make spring gardens and spring rockeries, and seem to be unaware of what a winter garden can be. Here, there has been a long succession of flowers, with Iris unguicularis flowering for three months, along with such species as alata, Histrio, reticulata and now boucharica. Many early tulips are in full flower, and many species, including biflora, Kaufmanniana (several with beautiful bright blotches of red), the "brilliant" Kaufmanniana, præstans, Eichleri and Hagen are in full bloom. Anemones have for long been very bright. Anemone blanda is in full bloom, and a few have already set seed. A. anguloss is

Digitized by Google

over, while A. Hepatica is still very blue and A. fulgens is a blaze of crimson; also A. Blue Bonnet among the nemorosas, with A. n. rosea, and grandiflora; while A. n. Alleni and Robinsonians have not yet opened. Primula Juliæ has been flowering and is still gay; and P. denticulata is perfection, and the garden polyanthus. In January and February the cyclamen attracted much attention, as did various winter-flowering ericas, which have never yet been without flowers since October. I omitted snowdrops and winter aconites, which flourish and add charm to the winter garden.—CHANDLER'S FORD.

CROCUS BIFLORUS.

SIR,—There is an unaccountable slip in the reference to C. biflorus as it appears in my notes in THE GARDEN of April 10th, *i.e.*: "(2) C. biflorus of gardens, according to Bowles probably a seedling form of C. versicolor."

In Mr. Bowles "Handbook of the Crocus," his reference on page 120 is as follows: "C. biflorus, as generally grown, is an old garden form, called the Scotch crocus, which most likely originated as a seedling in some Scottish garden and was introduced from thence into England and Holland. Nothing very closely resembling it has been found in a wild state, and like other old garden varieties it is sterile and increases rapidly by corm division."—T. ASHTON LOFTHOUSE, *Middlesbrough.*

GERANIUM FARRERI.

SIR,—I have grown this geranium for three years and have given it rather different treatment from that described by A. T. Johnson (page 207), and I think with equally good results. I have it growing in a moraine mixture on a southern slope, where it gets the sun almost the whole day long. It has shown no signs of forming runners, and one could hardly imagine that it could do so, but I notice this year that there are several seedlings of it coming up in the surrounding gravel. If these grow they will no doubt form the best means of increasing this dainty alpine.—R. B. COOKE.

PLANT NOMENCLATURE.

SIR,—The discussion on the naming of flower novelties is both very interesting and important; but, while agreeing with the desirability of suitable and attractive names, I think it is going much too far to expect that these should give clues as to colour. In some plants, where the number of new varieties is not very numerous, it might be possible, but in the case of many others it would be impracticable, as, for example, roses, daffodils, sweet peas, chrysanthemums, etc.

In my opinion, names should be brief and attractive, while the prefixes "Mr.," "Mrs.," "Miss," etc., should be avoided altogether; in fact, except for naming after the raiser or his special friends, the use of surnames might be dispensed with. It is easy to criticise, but it must be far from easy for raisers of novelties in many popular plants to find original and distinctive names. However, I think more use might be made of simple and appropriate nomenclature.

Personally, I think that names such as Colleen and La Tosca for roses are quite good, and I also like the Christian names adopted by Messrs. Allwood Brothers for Allwoodii, and the names of birds for the seedling dieramas raised by the Donard Nursery Company, and also for the new gladioli offered by Messrs. Ryder and Sons—they are attractive and, especially in the case of the dieramas, are appropriate.

Mr. Dalrymple asks for suggestions for his seedling freesias, and I venture to suggest the following for his consideration: Chaffinch, Bullfinch, Golden Oriole, Daydream, Merlin, Morning Mist, Pipes of Pan and Orpheus. These are just noted at random, and, in most cases, I fear Mr. Dalrymple would turn them down as not sufficiently indicative of the colour.

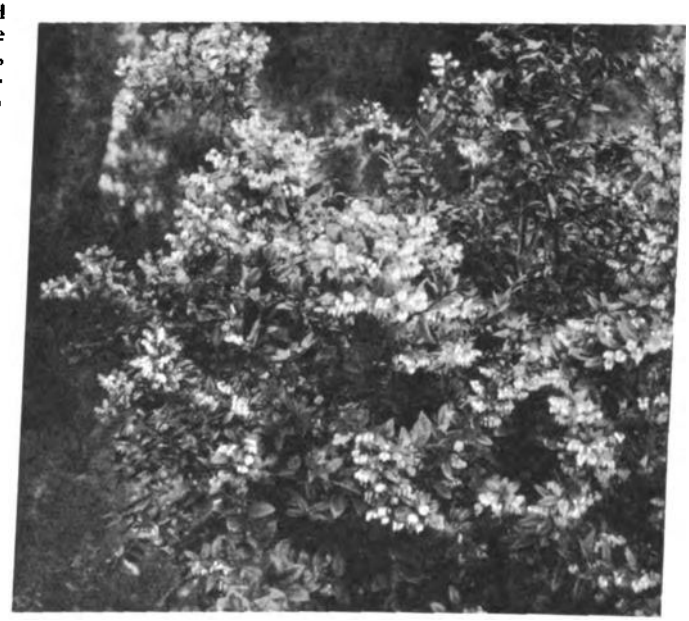
Personally, I do not care for such names as Carmine Queen, Crimson King, etc., as they really give little idea as to the shade and become far more confusing than those without any colour label.

These remarks, I am afraid, are not very original, nor are they particularly helpful, but I have tried to express my own personal opinion on a vexed and difficult subject.—CECIL M. BAILEY.

A RARE BUT BEAUTIFUL SHRUB.

SIR,—Not so long ago, while visiting a garden in Cornwall, I was introduced to a most attractive shrub which at first glance I took to be a pieris, but which I was later informed was a Pernettya ciliaris. The owner was, rightly, very proud of this plant, and, although there were many other fine things in the garden I thought this the finest.

It is a most attractive evergreen shrub, reaching, in this garden, some 3ft. or 4ft. in height, and of compact, upright and bushy habit. The leaves are bright green, ovate in shape, 1in. to 1½ins. long, and, what is most characteristic, as hard as boards. In addition, they are quite hairy. It is when in flower, however, that the full beauty of the shrub can be seen. When I saw it it was literally smothered with tiny white bells, borne in dense racemes after the manner of a pieris, and, I understand, the fruits are of much the same tone as its more common relative *P. mucronata*. It seems fairly hardy, as it was growing in the open, although sheltered from the wind, on the edge of a rockery bed, in well drained soil. I should think this must be one of the few plants of this species in the country, as in the "Hortus Veitchii" it says, when speaking of this plant, "a native of Mexico whence it was introduced. Now almost certainly lost to cultivation."



PERNETTYA CILIARIS SMOTHERED IN TINY WHITE BELLS.

It seems a great pity that such an attractive and ornamental evergreen as this plant certainly is should have been lost to our gardens, and I wonder if any of your readers may chance to know anything further regarding the plant.—SHRUB-LOVER.

POLYGONUM CAMPANULATUM.

SIR,—In writing of this attractive plant "A. G. F." does not mention that it is a most miserable thing without sufficient moisture. In a drought it is about the first plant to hold out signals of distress, even before Rudbeckia Newmannii and the phloxes. It is better, therefore, to plant it near water than in a herbaceous border, though if kept well watered it is certainly quite suitable for a border, as it does not run all over the place like some of the knotweeds.—M. F., *Gloucestershire.*

GENISTAS.

SIR,—In reply to Mr. W. Linders Lea, who asks me (page 179) how "genistas" in my district have fared this winter, I am happy to say that my own are none the worse, that is, assuming he is referring to Cytisus fragrans (Genista racemosus). Shrubs of this species have come through twenty degrees of frost with no more than a "singeing" of the tender tips and they are not against a wall. There is no doubt that C. fragrans is a good deal hardier than is generally supposed, but it is, of course, liable to have its flowers destroyed by spring frosts.

It may interest Mr. Linders Lea and others to know that the above specimens are among the survivors in a border containing Diplacus glutinosus, Malvastrum phœniceum, Cistus vaginatus and Olearia semi-dentata, all of which have been killed. Coronilla glauca, close by, only just escaped. I am afraid the particular shrubs of C. fragrans in the Conway Valley referred to by Mr. Linders Lea are unknown to me; some parts of that district do not enjoy the sea influence to the same extent as others.—A. T. JOHNSON, *N. Wales.*

THE PRUNING OF SHRUBS.

SIR,—In your editorial article in THE GARDEN of March 13th on the pruning of flowering shrubs, you ask readers to relate their experiences on the subject. As it is a particularly interesting and very important item in their cultivation, I would like to make a few remarks on the same, more in relation to the commoner sorts. The method the Editor followed in pruning the various kinds, very distinctly outlined in words easily understood, should be a safe guide for anyone to follow. In my opinion there are no points he gave which could be improved upon. I have for a long time noticed that the pruning of flowering shrubs has presented a mysterious and weighty problem to the beginner, and been a continuous bone of contention in the columns of the garden papers. To the experienced and practical gardener, accustomed to the pruning of various kinds of bushes and trees, it cannot for long present a great difficulty. A study of their different seasons of flowering soon enables one to know how to deal with them—what wood is to be cut back, left, or thinned out. In any case, close observation is required of different subjects, and more particularly those of recent introduction, in order to know them and become acquainted with their likes and dislikes, etc.

In pruning evergreens and deciduous shrubs, different methods must be adopted respecting each. We may take the evergreen berberis as an instance—such as B. Darwinii, B. Jamesonii, etc., and others of the same

Digitized by Google

type. Pruning of these should be done when they have finished flowering, and should consist in the cutting well back of old wood; a saw being used in the case of old specimens which have become top-heavy and the stems hard and bare. If possible they should be cut near to the ground to induce vigorous young wood to spring from the base or stems that remain.

Of the deciduous class, the philadelphus is a fair example; it flowers in early summer, but should not be pruned until winter or before growth starts in spring. The pruning consists of the wood being well thinned out to admit light and air, the branches regulated, cross and weakly shoots cut hard back. Spurring back of young wood should on no account be practised, as it would curtail the following crop of flowers. This method of pruning is applicable to diervillas (weigelas), ribes, etc. When cutting out the wood, however, an eye should be kept to the symmetry of the bushes to see that they are kept in shape and balance. We have, again, the forsythia, an early-flowering shrub; when it has finished flowering it should be spurred back annually to within a few buds of the old wood. This spurring will result in getting two or three strong and vigorous shoots from each spur which will flower next spring. Merely taking off the tips *as a matter of care* will do no good, and will only prove ruinous to the future of the shrub, making it top-heavy and exhausting it in a few years. If the plants be spurred as stated, they will have ample time during summer to make and ripen the wood thus made by autumn, which, if well ripened, should flower the following spring.

Olearias are evergreen, and should only be pruned to keep them in shape. O. macrodonta was cut to the ground with frost here last winter in exposed situations, but in well sheltered situations came through little the worse.

I have also noted what Mr. R. Moore, Thorp Hall, says in THE GARDEN of March 27th in relation to his experience with certain shrubs. Lavatera Olbia he cuts back every year previous to it dying back. We grow it on a wall here and find it retains its full growth over the winter. I am taking advantage of this trait and contemplate seeing it cover a large area of wall space with its great profusion of pink blossoms. The wood not dying back is a great advantage when one wishes to cover a wall. Thinning out of weakly and superfluous wood, and removing an old branch here and there, is all that I do for them. Some shoots are kept at full length as the plant flowers both on old and new wood. Mr. Moore, by allowing his Potentilla fruticosa to grow unpruned and not cut back year after year, and only making extension growths, would not assist in forming a shapely or flowering bush, as the want of cutting back is bound to make them become lanky and heavy at the top. I very much favour the Editor's method of keeping the knife on them annually, to thin out the growths and to induce them to replace the old wood with vigorous young growth. I hope I have made it clear that the cutting back of wood encourages the making of new wood on bushes and starts dormant buds into life—cutting to make wood which may flower.—WM. GRANT, *Crathes, Kincardineshire, N.B.*

SPRING PECULIARITIES.

SIR,—I was much interested in the article "Peculiarities of this Spring," in your issue of THE GARDEN, April 3rd, especially as to early rhododendrons.

Rhododendron præcox and R. Nobleanum were in full bloom here (Leicestershire) by the middle of February. They are growing on a steep bank with a south-east aspect, 500ft. above the sea, and their bloom lasted for nearly three weeks. Nobleanum was covered with exceptionally fine trusses of bloom of unusually brilliant colour, in spite of severe frosts and heavy snow in January. The bloom on all flowering trees and shrubs is remarkable this year, especially Magnolias Soulangeana and stellata, Viburnum Carlesii, etc.—ELLEN MURRAY SMITH.

IPOMŒA RUBRO-CŒRULEA.

SIR,—In answer to Mr. T. W. Briscoe's letter in the March 20th issue of THE GARDEN, I have grown this beautiful convolvulus for many years and have bought the seed from several of the well known firms; it has always come true, but has not done well every year.

Last year I had a specially fine show on about six plants, Sutton's seed, but I gave away more than this number to four different gardening friends and not one of these plants flowered, though all were taken from the same seed pan, this I think shows that the fault is not in the seed. I think red spider is the trouble, to which they are particularly subject.

I sow my seed in heat in March, pot up three in a pot in April, in the beginning of June I sink the pots out of doors in a warm corner, then re-pot and bring into the house again in late September; this gives me a fine show every bright day till the end of November, if red spider will leave them alone. I find that spraying with an insecticide does more harm to the plant than the blight.—H. HALCOMB HUGHES, *Belmont, Shrewsbury.*

SIR,—Having grown this ipomœa for several years, I gladly endorse all Mr. Briscoe says in its praise (page 178). No flower in the greenhouse comes in for admiration from visitors more quickly than this beautiful convolvulus. Its pure blue colour is so rare, though certainly evanescent. I have had an experience similar to Mr. Briscoe in getting seed of an ipomœa that was non-flowering, the plants grew strongly into a regular tangle, but never flowered. I did not put the blame on Learii, however, for I had some plants of Learii that bloomed all right, but it is a variety I did not care for. It is neither so free flowering nor the colour so fascinating as rubro-cœrulea. I have grown I. imperialis and had some very pretty flowers, pink and deep rose, and some daintily edged with white. I can recommend it.—J. P., *Glos.*

GREEN-FLY: A TROUBLESOME PEST

ALL GARDENERS SHOULD PAY PARTICULAR ATTENTION TO THE REMEDIAL MEASURES WHICH CAN BE TAKEN AGAINST THE DESTRUCTIVE GREEN-FLY SO AS TO ENSURE CLEAN AND HEALTHY PLANTS.

TO be "forewarned is to be forearmed." I must make an excuse for writing about these almost universal pests and this is the most appropriate excuse I can call to mind at the moment. Not only do I wish to forewarn readers, for everyone is well aware of the harm greenfly do, but I want to help them also to be forearmed.

I want, if I may be excused the liberty of transgressing on gardeners' valuable time, to devote a few lines to the life history of this very troublesome genus (or is it a family?). There is some variation from this life history among some species but the following will, I think, give a fair idea of how these small, but numerous and disastrous insects, live and multiply. In most cases the winter is passed in the egg stage; I have just been examining some of the small black shiny eggs to see what effect, if any, various washes have had. On the approach of warmer weather these eggs hatch out into nymphs or immature "green fly." Now these pests do not go through what we understand as the normal life cycle of insects, that is to say, that they do not change from egg to larva, larva to pupa (or chrysalids), and then pupa to imago (or perfect insects). Instead of that the grub continues to feed and grow and after moulting several times, reaches the mature stage. All the aphides produced from the eggs are females and they, when mature, give rise to another generation of females, the young being produced in a live state. For the first few generations only wingless offspring are brought into this world of plenty. When, however, doubt appears of plenty," then winged females, able to fly to other food plants, are produced.

Well, this process goes on (if nobody interferes with some beastly sprayer) until autumn, when both males and females are produced and the latter, after pairing, lay the eggs which are to tide the insects over the winter season. Just one more item. Aphides do not bite or chew, they simply force their proboscis into the leaf or shoot and suck up the sap of the plant, this, as I shall mention later is of importance when we come to deal with remedies.

Now for being forearmed. In the first place Huxley once said that "the uninterrupted breeding of ten generations of plant lice from a single ancestor would produce a mass of organic matter equivalent to the bulk of five hundred millions of human beings, about the population of the Chinese Empire"—just to give an idea of how quickly these pests do multiply.

Of course, even in a state of nature, "the uninterrupted breeding" never occurs. Rain will destroy a certain number, ladybirds and their larvæ (especially the latter) account for many more, while birds also devour quantities of them, to mention only three factors which work against "uninterrupted breeding." However, these natural checks are insufficient, in the majority of cases, to keep our plants clean.

I have heard it said quite frequently that "an east wind brings blight." The only way in which an east wind, or, for that matter, any wind, can bring blight, is to carry it from one plant or plantation to another. An east wind certainly does have an effect, but it is, I believe, in this way. A cold, drying east wind checks growth and weak growth is always more susceptible to attack than strong growth.

Before I go on to say anything about the actual spray fluids, I wish to emphasize the necessity to *spray early*. If only people will do that, then I can consider that this article has done its work. Of course, by spraying early I mean spraying as soon as the pest is seen; it is of no use spraying before there is any fly about (unless it be during winter,

Digitized by Google

when we use "Mortegg" winter wash to kill the eggs on fruit trees), as all the washes we use are intended to kill by contact with the insect itself and not by poisoning the leaf as for biting insects. Soft soap alone is effective if used with force, mixing 1–2oz. in a gallon of rain water and spray thoroughly. This is the best wash to use on very tender plants.

Forceful syringing with clear water will cleanse a plant, but it may only wash the pests to the ground or on to another plant, and in any case one is more sure when using a wash which if it touches the pest will kill it.

Among the washes it is possible to use with effect are various paraffin emulsions, which can be mixed at home, but these are somewhat dangerous unless one thoroughly understands their use and is very careful in mixing. Again nicotine may be obtained and one's own nicotine washes prepared, but here again great care must be taken to keep the fluid out of harm's way, for it is extremely poisonous. Notwithstanding the fact that most gardeners are also servants of "My Lady Nicotine," I have known the fumes from nicotine to make even moderate smokers to feel well—out-of-sorts—to be polite.

On the whole I think it is preferable for gardeners, more especially those who only use small quantities of fluid, to rely on one of the excellent washes which are manufactured by firms specialising in this business. One of the advantages of using these proprietary insecticides is that they are uniform in composition, and if one is careful to follow the maker's directions as to mixing, no harm to even tender plants need be feared.

Regarding the brands to be used, one may be satisfied that those firms advertising in THE GARDEN are offering reliable washes, and personally I favour "Abol" (which will also control rose mildew), "XL ALL" and "Katakilla," three washes which I have used most successfully.

For an amateur with only a few plants, that invaluable powder (which one only asks for when the shop is empty), "Keatings," will be effective if dusted over the "flies," or tobacco powder may be used with equal effect. N. D. H.

GARDEN TECHNIQUE

Notes on the Technical Side of the Garden and the Cultivation of Plants.

FLOWER GARDEN

CAMPANULA PYRAMIDALIS ALBA.

An Excellent Pot Plant.

THOSE who have sown seed of the chimney campanula early in the year should now have the seedlings pricked off into a box containing a medium fine potting compost. After being kept for a few weeks in a genial growing atmosphere, they should then be transferred to a cold frame. If given sufficient space in the box, no further shift will be required until August, when each plant should be potted singly into a 5in. pot, using ordinary potting soil. The plants should be put back into the frame and kept there until severe weather sets in, when they can be wintered in a house in which heat is available when frosts threaten.

In January the plants may be transferred to 7in. and 8in. pots, then kept for a few weeks in an intermediate house, afterwards removing to a cool house, and at the end of May plunging the pots in the open border. A few of the plants may flower in the autumn.

Those that do not flower should be accommodated in 10in. pots, about the middle of October, and wintered once more in a cool house. In the spring the plants will grow apace and should be assisted periodically with artificial manure applied with the water.

In June the flower spikes should be supported with 3½ft. and 5ft. stakes, and the plants spaced out, when, later on, they should be set in the conservatory or show house. The plants here commenced flowering in July, and one of the number—from base of pot—stood over 8ft. high and carried thirteen flower spikes.

In the cultivation of these campanulas, avoid pinching if large, handsome plants are desired. Pinched plants throw a larger number of flower spikes, but these are weak in comparison with the unpinched plants.—DAVID ARMSTRONG, *Midlothian.*

PROPAGATION OF DAPHNE GENKWA FROM ROOT CUTTINGS.

THE usual method employed in propagating Daphne Genkwa is by grafting on Daphne Mezereum. An interesting experiment, however, has been tried in propagating this daphne by means of root cuttings. The plants from which the root cuttings were taken had originally been raised from layers. The roots, being of a fleshy nature, seemed to suggest a ready means of propagation, which later proved fairly successful.

The treatment of the root cuttings was as follows: In January small pieces of root varying from 2ins. to 5ins. in length were laid horizontally in a box of sandy soil. A few of the shorter and thicker pieces were inserted upright. The box was then placed on a stage over bottom heat. Careful attention was paid to watering, and the soil was kept slightly moist. If too much water had been given there was a tendency for the roots to rot owing to their soft nature.

ROOTED CUTTINGS OF DAPHNE GENKWA.

Within a month buds developed on a few of the roots, and in most cases one bud to a root. One root, however, produced two buds, and both made good growth.

The roots were allowed to finish their growth in the box before being lifted and potted. At the time of potting, which was in August, the tip of one plant was cut back, and shortly afterwards the two buds at the apex developed short lateral branches with small flower clusters at their tips. It is unusual for this daphne to flower in August, as the usual period is from April to May.

By the middle of March the plants were in full bloom, the stems being covered with lilac-coloured flowers. The growth attained in the first season by the root cuttings was about 12ins.

It is not advisable for one to interfere with an established plant, as in all probability it will be a grafted plant, and in addition daphnes dislike being disturbed after they have established themselves.

Another plant which is closely allied to the daphne family, namely, Dirca palustris, can also be increased by means of root cuttings.—H. H. BRYCE.

ROSES: MANURING OR FEEDING AND STOPPING.

THE long spell of cold weather stopped the bursting of the buds at an early date; but directly milder weather came, especially the warmer nights, the buds burst forth and soon became clothed with leaves, some pale green, others deep red. At the ends of these shoots one can see the tiny flower buds already forming, and so this is the stage when some food may be applied with much benefit. If the roots are carefully examined, it will be clearly seen that a network of young fibrous roots is now forming. Stimulants, applied in moderation, will do a lot of good from now on until the end of June. It is much better to feed now than during the winter, as then the roots are not active and cannot benefit. Diluted liquid manure is very beneficial; also bone-meal and concentrated rose tree manures, as sold by advertisers in this journal. This is also the time for applying neat surface mulches to conserve moisture around the roots. A flush of blossom comes towards the end of June, then there is a scarcity in July; but if the following plan be adopted, there need not be any lack of blossom in the latter month. The young shoots of hybrid perpetuals and hybrid teas should have the tips pinched off about the last week in May and until June 9th. More young shoots will grow from the stopped ones, and they will bear very neat flowers about six weeks later—mid-July to the second week in August.—GEORGE GARNER.

NEMESIA SUTTON'S HYBRID BLUE GEM.

THERE are many choice and coloured varieties among the nemesias which are eminently suited for decorative furnishing in the flower garden. Some care, however is required to grow nemesias properly before they are ready to set out in the open ground.

At this time of the year the seedlings should be pricked off into boxes and kept in a genial growing atmosphere until re-established in the soil; afterwards they should be gradually exposed to cooler quarters as growth advances. The aim should be to grow the

Digitized by Google

plants sturdy, by keeping them well aired and under cool conditions such as those provided by a cold frame, until they are permanently set out in borders by the beginning of June.

A bed of about fifty plants of the light blue variety called Sutton's Hybrid Blue Gem provides the most charming effects. Well grown plants of this variety range from 12ins. to 18ins. in height, and produce flower heads 8ins. in diameter.—DAVID ARMSTRONG.

THE GREENHOUSE

GESNERAS.

THESE are lovely plants for furnishing a warm greenhouse or conservatory; they possess exceptionally beautiful foliage, much more beautiful than that of the gloxinia, although the leaves are somewhat similar in texture. The flowers are borne on strong stems and form pyramids of blossom on well grown specimens. The colours emanating from the newer strains are remarkably beautiful. The foliage is massive and quite hides the flower pots, also the stage on which they are placed. Seeds should be sown in much the same way as those of tuberous begonias or gloxinias. The ideal compost for the seeds is one made up of well rotted loam and old leaf-soil in equal proportions, with sufficient clean coarse sand to render it all porous and sweet. Provide sound drainage in a pot or pan; three-parts fill the pan with the compost, make it moderately firm, water, and one hour later sow the seeds on the surface, gently pressing them into the soil. Cover with glass and paper until the seeds germinate, then gradually expose to light but not sun. Duly transplant and pot on the seedlings. Seeds may be sown now, and tubers may also be started by slightly burying them in the surface of a similar compost, but of a rougher or more lumpy nature. Plant several tubers in each pot so that there will not be any need to repot. Do not overcrowd, and be careful not to over-feed or over-water, and be especially careful not to wet the foliage. Many years ago I first saw a fine batch of plants grouped on a conservatory floor, and I thought they were very charming, so arranged.—HANTS.

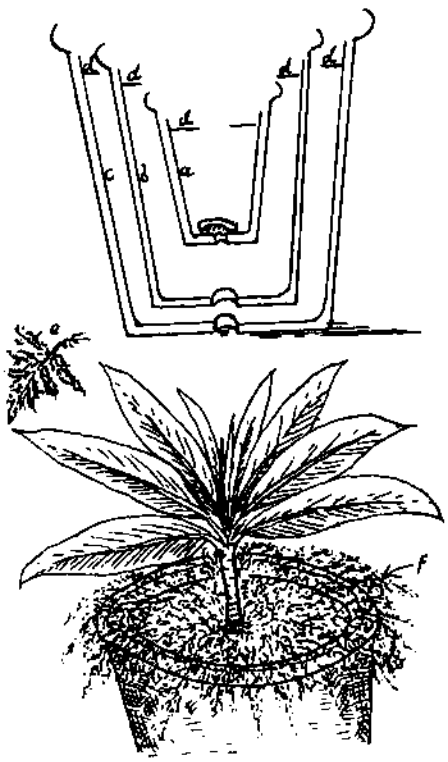
PRIMULA MALACOIDES.

WE find greenhouses built in almost every conceivable position. Some are very hot in summer, others rarely receive any sunshine. To fill such structures satisfactorily we must grow those kinds of plants that do best in sunshine or shade, as the case may be. This small but profusely flowered primula is a gem for growing in the sunless structure, provided there is plenty of light—and the latter is available if there are no very high buildings or trees near. Sow seeds now in a pot or pan in preference to a box, as there is a more constant moisture around the tender roots in pots, and this is very beneficial. The compost should be half loam and half leaf-soil with sand; or, better still, if available, some good old mortar rubble. The pots or pans should be clean and dry inside when used. Place the compost on perfect drainage and level the surface; water, then drop the seeds about half an inch apart and very lightly cover them. Place the seed vessels in a shaded part of the greenhouse. As the seedlings become fit for transplanting, transfer them to a larger pan or several pots, and in due course pot them singly in small pots. From this stage till next October the best position for the young plants is one on a bed of ashes in a cold frame. Get the plants established in 5in. and 6in. pots as soon as possible, using a similar compost with the addition of a small proportion of rotted manure. Ventilate judiciously, be careful about watering and feeding, and keep the foliage always dry.—GEO. GARNER.

MISCELLANEOUS

POTTING PLANTS.

FROM early in April to the end of June there will be a lot of potting and repotting work done in gardens, both large and small. Not only should the cultivator understand how to pot and repot a plant in the first instance, but he should provide suitable composts. I have seen greenhouses filled with the stumps of plants in very large pots, the latter containing a few decaying roots and loose, fibreless soil taken in the first instance from the vegetable garden borders. Mostly, it is worse than labour in vain; it means devastation as far as plants are concerned. If some good old fibrous turf cannot be obtained and duly rotted, then it would be wise on the part of the cultivator to buy a few bushels of



compost ready mixed from a near-by nursery. The turf and some sweet leaf-soil will combine with coarse sand to form a good general compost. In the first instance many seedlings will require potting. They are placed singly in small pots similar to the one shown at *a*, and the soil must not be pressed down too much, as their roots and stems are so brittle. The first repotting should, usually, be into a larger-sized pot than may seem necessary—into pot *b*. Then the third repotting should be into pot *c*, as shown, each time observing space left for watering, shown at *d*, *d*, *d*, *d*, *d*. If plants are being grown for placing in vases on tables or in halls, such specimens as crotons, dracænas and ornamental grasses, with small palms, may be covered with selaginella moss after the final potting. Small pieces of this moss, as shown at *e*, should be laid on the soil in the pot, shown at *f*, and a small quantity of fine soil placed on to half bury the moss. If kept in a moist state the selaginella soon grows and forms a lovely green cushion entirely hiding the top of the pot. This should not be done in the case of plants generally.—CHRISTCHURCH.

AN EFFICIENT SPRAY.

WE have not yet reached the time when we can say that any one spray fluid is the elixir of immunity to pests; but it is possible to be discreet, and so reduce the actual work necessary in preventing pests from assuming outrageous proportions.

From long experience we have decided that two applications about this time do more good than several sprayings at other times against certain pests—one just before the buds begin to open on apples and pears, and one after the petals fall.

The spray fluid we recommend is a combination of lime, sulphur and nicotine. The concentrated lime-sulphur is diluted to the proper strength as indicated, then this is treated as water and the requisite proportion of nicotine added. As several nicotine concentrates of varying strengths are sold, we can merely quote one example in which ½oz. of the nicotine is added to each 4 gallons of lime-sulphur wash.—CLYDESDALE.

WHITE FLY.

QUESTION.—Does white fly live on plants throughout the winter under glass?

Answer.—Yes, it lives on weeds, if there happen to be any growing in pots or borders, as well as on cultivated subjects—such as roses, chrysanthemums, cinerarias, begonias, and sweet peas—and on the rooted cuttings of many kinds of plants.

Question.—Should attempts be made to get rid of the fly during the winter months; if so, how should an amateur cultivator act?

Answer.—Certainly, every effort should be made throughout the winter to eradicate the fly. Indeed, much success will follow any careful, judicious attempts. First, be sure that those plants that are unable to withstand the action of several proprietary fumigants are taken to other houses or buildings while the structures containing the fly are fumigated or vaporised. Usually, the plants that should not be subjected to the fumes are named on the packets containing the remedies. Care should be taken that such plants are free from fly before they are returned to the house after it has been fumigated. If there are any remains of old crops, such as those of tomatoes, being cleared away, it is a good plan to syringe thoroughly the stems, old leaves and surface of the borders with paraffin emulsion. I use pure paraffin vigorously stirred up in clear water for this purpose, and it kills all the insects it touches while preventing others flying and leaving the old plants. Then the latter and the surface soil may be conveyed to the garden fire. Following this action the house can be treated with white fly remedies as advertised in THE GARDEN. White fly soon breed wholesale on young vegetable marrow plants, cucumbers, schizanthus, melon plants and the common buttercup, so we see how important it is that the plants start clean.—G. G.

NOVEL PLANT SUPPORTS.

SOME plants, like mignonette, have such very soft stems that they will not stand much in the way of tying to supports. Ordinary metal meat skewers have in these cases proved very useful for holding up the stems. The ring at the top was opened out a little and then bent over at a right angle. After pushing a skewer into the ground the stem was gently brought into the ring, where it was securely, but not tightly, held. Being galvanised, the meat skewers do not rust, and they will last for an indefinite time.—S. L. B.

WORMS—AND WEEDS

TO clear these pests from your lawn, bowling or putting green:—Brush or rake away the worm casts. Scatter **Cooper's Powder Wormkiller** evenly over the turf during damp, dull, warm weather, and water the ground thoroughly. The worms will come up to the surface, and then all you have to do is to sweep them up and bury them.

The "worm cast" nuisance is over, but you still have the weeds, and other rank growth to consider. After using the Wormkiller, let the ground dry thoroughly, then apply **Cooper's LAWN SAND** which will destroy all daisies, dandelions, etc., which disfigure the lawn. Cooper's Lawn Sand also acts as a lawn food, assisting growth and distribution of the finer grasses.

Further particulars are given in our leaflet, "REMARKS ON THE LAWN," which will be sent free on request.

VEGETABLE GARDEN

PLANTING ONIONS.

PROBABLY many readers experience great difficulty with their onion plants during the growing season, particularly during the months of May and June, owing to the ravages of the onion fly maggot. My experience with onion fly is that eggs are deposited under the base of the plants, and not among the scale leaves and for this reason plant fairly deep, insert the base of the stem, for at planting time there is no bulb, about 2ins. below the surface; plant in firm soil and pack the soil firmly among the roots, leaving the surface loose. Keep the Dutch hoe going continually when the ground is dry and feed during June and July with dressings of artificial manure. A good fertiliser for onions consists of 1½lb. sulphate of ammonia, 3lb. superphosphate of lime, and 1½lb. sulphate of potash, mixed together. Give the plants the mixture in two applications to 30 sq. yds.

After the fly period is over, remove the soil from around the bulbs to allow them to swell, swelling of the bulbs generally taking place about the end of July and early August, according to the variety and season. —G. S., *Edinburgh*.

THE CUTTING OF SEED POTATOES.

ONE occasionally meets with those who are afraid to cut their seed potatoes in case of failure—and those who do cut, dust with lime or flowers of sulphur before planting. Many fail to appreciate the fact that if a potato is cut the tuber forms a corky layer so that lime or sulphur is unnecessary.

Last year I conducted a small experiment with three well known commercial varieties. All the potatoes were planted in drills 2ft. 3ins. apart and the sets 12ins. apart in the drills. Artificial manure was applied at the rate of 7cwt. per acre—2cwt. sulphate of ammonia, 3cwt. super-phosphate of lime, and 2cwt. sulphate of potash, together with 20 tons farmyard manure. The soil was a light loam containing very little organic matter.

KERR'S PINK.—Whole sets planted, weighed when lifted 5 tons 15cwt. per acre, while cut sets weighed 6 tons 2cwt.

RHODERIC DHU.—Whole sets and cut sets planted, each weighed 9 ton 3cwt.

FIELD MARSHAL (a russet Up-to-Date).—Whole sets planted weighed when lifted 7 tons 4cwt., and cut sets 8 tons 9cwt.

While it is not advisable to base exact conclusions on the result of the experiment, it is evident, however, that by cutting fairly large potato "seed," the yield is not reduced on light soil.—G. S.

PEAS FOR SUCCESSION.

I WONDER how many amateurs, who do all they possibly can, succeed in obtaining a regular supply of tender peas after the first batch is exhausted? They rarely begrudge the time spent in growing the first lot of peas; their minds are fixed on varieties, site, soil, manures, sticks and feeding and the reward is a splendid lot of early peas. But afterwards, very frequently, a break in the regular supply comes. To obtain an unbroken supply of tender green peas is, I admit, a difficult matter sometimes and expert cultivators often meet with failure. But we must not look for failure, so let us see what should be done to secure success. Where good soils obtain it is unwise to use much organic manure; where they are poor, I favour the use of a moderate dressing of well rotted manure to obtain some substance in the haulm, and where soils are heavy in character, mix with them free dressings of wood ashes and burned rubbish, with a small percentage of burned soil. Now, as regards varieties; we all have our favourites, but for the benefit of the inexperienced, I will name a few reliable sorts. Earliest of All, Laxtonian, Peter Pan, The Pilot, Gradus. These may do for the first pickings, which should be available late in May and till mid-June. To follow them we may sow seeds of Daisy, more of Gradus, Fillbasket, Edwin Beckett, The Bell, Alderman, Gladstone, Mainstay, Standard and Veitch's Perfection. Again, where soils are difficult for late crops, seeds of Laxtonian and Peter Pan, sown during the early part of July, will result in very useful crops with the haulm comparatively free from mildew. The variety Ne Plus Ultra is a grand late pea in some districts, but it is unwise to depend upon it, owing to proneness to mildewing. The great difficulty in pea cultivation comes during midsummer, generally. To combat drought, deep cultivation of the soil and surface mulching without stint should be the rule.—GEO. GARNER.

LATE WINTER GREENS.

WE rarely realise the importance of a good batch of greens from March to June as fully as we should do, until we are faced with a scarcity during that period. Really we should concern ourselves with the matter at once and strive to prevent it. To do this we should provide, now, a nice batch of plants in variety both as regards kinds and sorts, and also make provision for the final planting in due course. A few seedling Brussels sprouts transplanted in a nursery bed in readiness for planting out as soon as early potatoes are lifted will fill a big gap. Late broccoli, including June King, will also turn in most useful when greens are scarce. Both the white and the purple sprouting broccoli should be freely grown. Several kinds of greens are allowed to make secondary shoots, but these are mostly woody. This does not happen in the case of the sprouting broccoli—it is always tender.

J·P SUPER

"Worth the extra cost"

"IT took a man and a boy," writes a J.P. user, "two days to mow lawns with old machines. Now *the man* can do them all in *one* day."

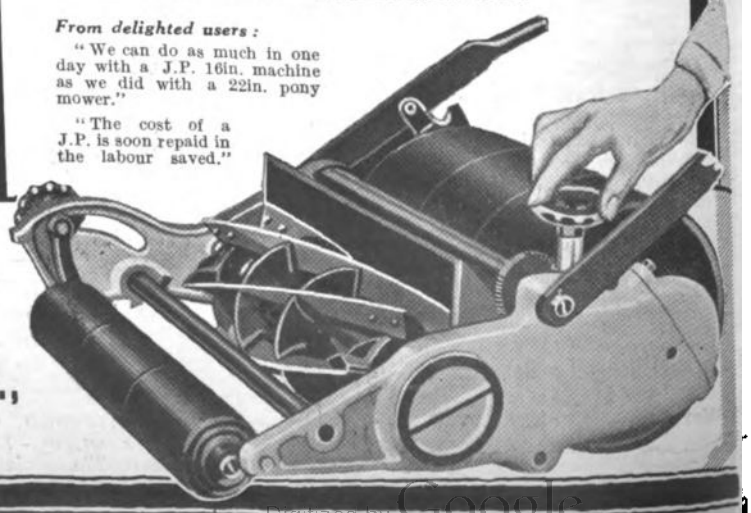
Could anything be more conclusive or convincing than this simple statement of fact?

It is a real economy to pay a little more for a mower which is so infinitely better. Its patented time and labour-saving features—such as hand-wheel adjustment of cutters (shown in illustration)—render it ahead of all in value.

From delighted users:

"We can do as much in one day with a J.P. 16in. machine as we did with a 22in. pony mower."

"The cost of a J.P. is soon repaid in the labour saved."



free *Send for Booklet describing unique patented features and ask for demonstration.*

KNAP HILL NURSERY
WOKING STATION, SURREY

SOME AUSTRALIAN TREES

EARLY in the warm month of December (midsummer) in New South Wales one of our numerous handsome evergreen trees, Elæocarpus cyaneus, is laden with thousands of white, fringed flowers, and for two or three weeks, followed by vast quantities of fruit, which, when ripe, become a beautiful dark blue, ovoid in shape and about half an inch in length, but of no value whatever for consumption. It has several local names, such as wild sloe, native olive, white boree and white bark.

Generally speaking, this tree is small, about 30ft. or so in height, frequently much less, but sometimes under favourable circumstances it attains a height of about 60ft. Its favourite habitat is among the sandstone rocks along the New South Wales coast, and oft-times in the poorest of sandy soil. It thrives well under cultivation, when it becomes remarkably conspicuous and beautiful when in full bloom. It is but seldom made use of, however, for ornamental purposes. There has been a prejudice until quite recently against anything indigenous, unfortunately, and most beautiful trees and flowering shrubs are recklessly destroyed, to give place to exotics, many of which may never succeed.

There are several species of the Tiliaceæ Order, to which the above belongs, one of the most handsome being E. grandis, which grows to great perfection in the semi-tropical north-east coastal district of New South Wales and in Queensland. Its local name is blue fig, the aboriginal name being cooloon. It bears innumerable white fringed flowers, larger than cyaneus, and its handsome fruit attains a size of about an inch or more in diameter. This tree attains a height of 80ft., more at times, and its timber is useful for many purposes.

Another species, E. obovatus, known locally as ash, pigeon-berry tree, attains a great height, sometimes 130ft., with a diameter of about 5ft. The timber is light and is used for making oars, etc. It was first discovered on an alluvial island near the mouth of the Hunter river, about seventy miles north of Sydney. The discoverer

ANTIRRHINUMS

IT'S only the fact that we grow and deliver especially good plants that we wish to advertise. The brightness, the long-flowering life, the wonderful adaptability of Antirrhinums (Snapdragons) are known to everyone. Although our plants are properly grown, transplanted, well rooted, hardened off, in all ways particularly good, as becomes a firm which reckon to do things well, the price is only

considered this tree to resemble the English ash, hence the local name. The island was named Ash Island, which it has retained.

Probably E. cyaneus would succeed very well in warm coastal localities in Great Britain, and it is well worth a trial. Of course, for all I am aware, it may have been introduced and made use of for ornamental purposes.—WALTER S. CAMPBELL, *Sydney, N.S.W.*

WE have pleasure in announcing that in consequence of the increase of his business, Mr. Alfred Dawkins, Seedsman, King's Road, Chelsea, so well known to many of our readers, has taken into partnership Mr. Donald Blaxill of Colchester.

Mr. Blaxill was for some time a student at Wisley and afterwards served with Messrs. Dobbies and Messrs. Watkins and Simpson. He holds the National Diploma in Horticulture (Seed Section).

Mr. Dawkins will continue to give to the business his active interest and attention and it will continue to be carried on under the name and style of Alfred Dawkins.

WE are pleased to hear from the Netting Department at St. Dunstan's that the result of the advertising of the garden, farm and sports nets made by the war blinded men, has brought along a considerable number of orders and many enquiries. The late Sir Arthur Pearson always maintained that "a blinded soldier busy is a blinded soldier happy," and we feel sure that our readers will send along all possible orders for the excellent work produced by these sightless craftsmen. An enquiry to the Netting Department (A), St. Dunstan's Headquarters, Inner Circle, Regent's Park, N.W.1, will bring all details and a price list.

CATALOGUES RECEIVED.

ONCE more the season has come round when attention must be given to the bog and water garden and an inventory taken of its inmates. Many of the old plants may require to be renewed and a few new kinds introduced to provide a variety and add a freshness to the scheme. Where there exists some doubt as to what to plant, we should suggest a look through Messrs. Perry's new list of hardy plants for the water and bog garden. It is a well illustrated little brochure and offers numerous subjects for providing decorative effects in this part of the garden. A wide selection is offered in water lilies suitable for all sizes of lakes and pools, and, in addition, many other ornamental waterside plants are fully described. It is a list which the majority of gardeners who are interested in this branch of gardening will find of the greatest interest and service at this time.

KILL those WEEDS!

HOEING & HAND-PICKING OF WEEDS ARE BACK-ACHING, TEMPER-TRYING JOBS.

WHY NOT SAVE TIME & TROUBLE BY CLEANING THE PATHS WITH

COOPER'S Weedicide

("Highly Commended" by the Royal Horticultural Society)

1 gallon of Weedicide (price 9/-) dilutes to 100 gallons water; the cost of the ready-for-use mixture is, therefore, about 1d. per gallon, and is sufficient for treating 300 to 400 square yards.

1 pint 1/9 1 quart 3/- ½ gallon 5/- 2 gallons 17/- 5 gallons 36/6

IF YOU PREFER TO USE A NON-ARSENICAL WEEDKILLER, WE RECOMMEND

McDOUGALL'S

PERFECT SAFETY WEEDKILLER

Involves no danger of poisoning to Domestic Animals, Poultry, Game, etc.

1 pint 1/6 1 quart 2/6 ½ gallon 4/- 1 gallon 6/6 5 gallons 25/-

Write for our Illustrated Leaflet, "THE WEED PROBLEM SOLVED" and you will learn how weeds can be eradicated quickly and easily.

If unable to obtain these Weedkillers locally, please write :—

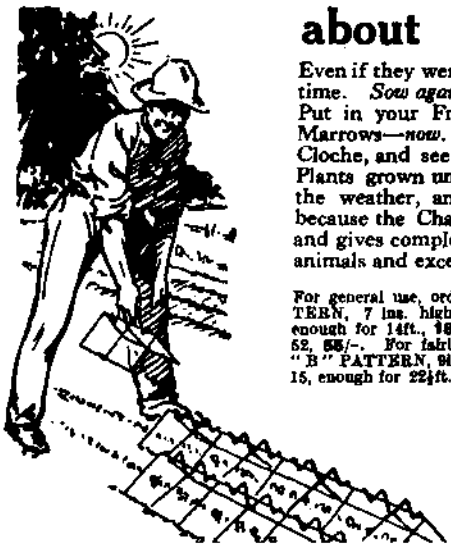
THE BRITON FERRY CHEMICAL & MANURE CO. LTD. (Dept. E), Briton Ferry, South Wales. (Est. 1888.)

Don't despair

about those early sowings



Even if they weren't a success, you can easily make up for lost time. *Sow again now*—and use the Chase Continuous Cloche. Put in your French Beans, plant out your Tomatoes and Marrows—*now*. Then cover them with the Chase Continuous Cloche, and see how quickly they will grow big and sturdy. Plants grown under Chase Continous Cloche thrive whatever the weather, and mature weeks earlier than in the open, because the Chase Continuous Cloche traps all the sunshine and gives complete protection against cold winds, frost, birds, animals and excessive rain.

For general use, order "A" PATTERN, 7 ins. high; box of 12 enough for 14ft., 18/-; 24, 35/-; 52, 65/-. For fairly large plants, "B" PATTERN, 9in. high; set of 15, enough for 22½ft., 35/- 80, 60/-

Free Booklet (explaining how the Chase Continuous Cloche saves labour, time and seeds, and ensures bigger, better crops) is gladly sent on request. Send a postcard *now* to

Chase Continuous Cloche
A Ray to catch the Sunbeams
(Dept. 7), CHERTSEY, SURREY

Carriage paid to nearest station in England and Wales; 1d. in the 1/- extra to stations in Scotland, Ireland, Isle of Man, Isle of Wight and Channel Islands. F.o.b. for colonial and foreign countries.

NEW HARDY CRIMSON BROOM

AT Chelsea Show (1925) the King said, "That red Broom is certainly very striking." This was the new crimson Broom "Dorothy Walpole," which received the unanimous Award of Merit from the R.H.S. as well as other distinctions in London and on the Continent.

In the "Field," a well known ex-Curator of Kew Gardens wrote: "The richest coloured Broom known is one named 'Dorothy Walpole.' It is as hardy as the common Broom . . . and is very free-flowering . . . the colour is rich velvety crimson . . . more attractive than any of the coloured Brooms yet seen." The colour far surpasses Cytisus Dallimorei, and the growth is as vigorous as C. Andreanus; it requires no special treatment nor any kind of protection whatever—just a hardy shrub for ordinary garden soil in any part of the British Isles, however far north.

A Vice-Chairman, Floral Committee, R.H.S., wrote: "Everyone who has seen my plant has been astonished at its warm glowing red," and from a lady in Devon: "I am so delighted with the Broom 'Dorothy Walpole.' It has done splendidly and is like a sparkling gem in the garden—one mass of flower."

Strong pot-grown plants now ready for planting out, to flower in May, 12/6 each. Carriage paid rates to any station in Great Britain or Ireland: One plant, carriage paid, 15/-; two plants, carriage paid, 28/6; three plants, carriage paid, 41/-; six plants, carriage paid, 79/6.

NOTES ON PRIMULAS—I

THE primula stands among the foremost of plants that are becoming known as more and more worthy each year. This is particularly the case with Asiatic species. Their quality has been recognised in the past by a few, but in many cases their requirements have not been understood, so they have been labelled as difficult plants. Even now, when they are so much admired at flower shows and in various gardens, the average gardener is afraid to come to grips with them and is inclined to leave them severely alone. He is wrong—of course I must make an exception in what I say of the Candelabra group, such as japonica, Beesiana, Bulleyana, pulverulenta, Helodoxa, burmanica and so on, those, in fact, which send up spikes or whorls of flowers in tiers, for these have already achieved a considerable popularity through ease of growth, free-flowering habit and general suitability. They are sturdy and hardy and, provided that they have sufficient moisture, they are not only perennial in habit, but seed themselves freely. Even they are not sufficiently grown; there should be masses of them in every garden.

I find that half the battle with these Asiatic primulas is to keep them free from weeds. It is hopeless to expect much of them in ground clogged with vegetation. They like space, among rocks if you like, for they help to conserve moisture and keep the roots cool, quite an important consideration. They like moisture and, I think, good subsoil drainage, although at the Royal Botanic Garden at Edinburgh they have flourishing colonies of many species in the marshy low ground near the lake. However, I am sure that if drainage is deficient, more care must be taken over the composition of the soil in which they are planted and, also, they do not increase so readily. They also require a certain amount of shade, although the cooler the roots are kept the less shade is necessary.

I grow practically every species I have in ordinary loam, if anything on the heavy side, in clefts and pockets on the rocky sides of a stream. The drainage is excellent and they are kept cool and moist without the soil getting stagnant. I may be lucky in having such a situation, but almost every garden I see has some corner where Asiatic species would flourish. A stream is fortunate, but it is not a necessity. At any rate, under these conditions practically every species that I have tends to increase. One plant of sino-purpurea planted two years ago, has now nine crowns, a capita four years old has eleven, a candelabra of Kingdon Ward's two years planted has no fewer than thirteen, secundiflora two years old has eight; even such a difficult plant as P. melanops of the muscarioid group, planted last spring, has now two crowns. I put this down partly to moisture in the atmosphere from the stream, but mostly to good subsoil drainage and because they are not crowded. I plead no special knowledge, for I only became really interested in primulas three years ago, nor to special care, for I only see them about four times a year. The only things I do are to prevent crowding, aerate the soil each spring with a hand fork and leave it fairly loose around them. So far I have not bothered about dividing them, but this year, although not a single crown has died, I shall have to do so. The time to do so is after they have flowered.

Although I have by no means a large collection and about half of what I have are untried, yet they are sufficiently representative to form some opinion of the very debatable point as to whether primulas should be raised from seed each year. Here I must walk warily, for even experts differ, but I should certainly say that it depends upon circumstances and that no golden rule can be given. The real tinies, such as bella and moscophora, can be left out of the question, for they all have the strongest objection to whatever we can offer them in the way of growing conditions. They may flower from imported seed, but they will neither survive nor set seed here, so they can be ruled out. The main reason why others of more reasonable size fail to survive is not because they are monocarpic, which they are not, but because the crown rots during the winter and so the plant dies. This rotting may be caused either through insufficient drainage or, what I think is even more important, from the resting crown being covered with damp, rotting vegetation. This is one reason why weeds should be eliminated. It is also a good plan to remove carefully their own dead foliage as soon as it has withered. It is really an error to coddle primulas with the mistaken idea of keeping them warm. It is much better to have the bare earth around them during the winter. I think that another cause of the crown rotting is too deep planting, an error which causes more damage to all kinds of plants in the garden than any other manual operation. It is far better to plant primulas too shallow than too deep, for it is easier for a plant to pull itself down than shove itself up.

AMONG THE ARTICLES IN OUR NEXT ISSUE WILL BE:

NATIVE PLANTS IN OUR GARDENS, by Dr. Lloyd Praeger.

THE DRY SUNNY BANK, by J. Birkentall.

Digitized by Google

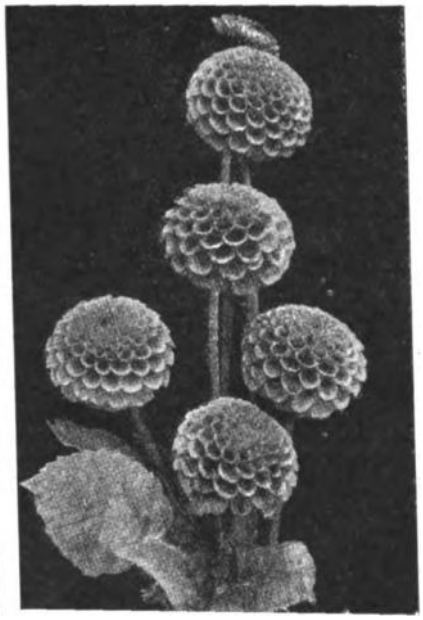
THE RETURN OF THE DAHLIA

THE first severe frost that strikes down the dahlias leaves a note of sadness in the garden. What was yesterday a blaze of colour is to-day a blackened, pulpy mass of shrunken foliage and flowers. During the last two or three years the Frost-spirit's stroke has come about the third week in October, but as this is nearly three months after the date when the first bloom can be gathered, it is hardly fair to say—as many critics do—that the fault of the dahlia is its short blooming period.

Last season I had a large collection of dahlias comprising all sections and numbering one hundred and thirty plants. During September and early October they made a perfect kaleidoscope of colour.

Now is the time to ask, "Have you experienced the pleasures of dahlia culture?" They are very easy plants to grow. All they need is a well cultivated plot, forked over in spring and enriched with a liberal dressing of well rotted animal manure and bone meal, an open, sunny site that is fairly well sheltered from prevailing winds, but not overhung with trees, and necessary protection and staking. If the site has previously been manured, say for a potato crop, all that is necessary is to clear it of surface weeds, and mark out the positions to be occupied by the plants. Dig out a hole about two or three spits deep, mix a little animal manure in the bottom and some bone meal and superphosphate in the upper layers as the soil is replaced, pressing the disturbed soil down firmly. Plants should be well hardened off before planting out in late May or early June, and if danger of frost is not over, protect the plants by means of inverted pots at night. Stake early and tie securely, afterwards repeating the tying up as the plants develop. In light soils a mulch is beneficial in a dry season. Dahlias revel in moist conditions at the roots and a sunny sky.

TYPICAL OF THE STAR TYPE.



AN ATTRACTIVE POMPON VARIETY.

A FINE SINGLE DAHLIA.

TYPES TO SELECT.

Cactus dahlias are mainly exhibition flowers, superb when well grown, but generally a failure as decorative plants. The following are the best decorative kinds:

Arthur Pickard, pinkish salmon with lighter tips; Border King, scarlet crimson; Conquest, crimson maroon; Constance, rich rosy pink; Cygnet, yellow with scarlet stripes and spots; Edith Carter, yellow suffused carmine; F. W. Fellowes, orange scarlet; Honesty, white changing to pale pink; Ivory White, a name descriptive of the colour; Mary Purrier, crimson scarlet; Mrs. A. Harvey, light salmon pink; Patriot, crimson scarlet; Sweet Briar, rosy pink; and Wild Rose, pink with lilac tips.

COLLARETTES.

These are mostly useful for decorative work, either in the garden or indoors. They are single flowers with a collar of shorter petals coming from the base of the outer petals. The following is a good selection: Admiral, blackish maroon with white collar; Agathe, creamy buff with rose tints, collar cream and white; Circe, white suffused lavender, white collar; Clarice, silvery pink with white tips, white collar; Doon, orange scarlet, bright yellow collar; Eclipse, reddish crimson edged yellow, yellow collar; Gipsy, maroon edged rosy crimson, white collar; Gold Tip, scarlet and gold with gold tipped collar; Ivor, orange scarlet, collar yellow suffused scarlet; Janet, crimson, collar white edged crimson; Lolah, brilliant scarlet, yellow collar, a very fine variety for massing; Scarlet Queen, intense scarlet with deep yellow collar, one of the finest varieties in commerce; and Verona, coppery red, collar red suffused yellow, a very fine variety.

THE PEONY-FLOWERED TYPE.

These are very large, semi-double flowers, not formal like the cactus or show dahlia, and very popular for garden decoration. They are too heavy for effective arrangement in vases.

The most outstanding kinds are Orpheus, reddish salmon heavily suffused buff; Albina, white; Angelos, yellow suffused scarlet; Blazer, brilliant scarlet; Brightness, one of the best; Candida, white, medium sized flowers on strong stems; Corban, bright salmon red; Crusader, salmon rose on white; Edith Cavell, old gold shaded reddish bronze; Enchantress, pure silvery pink, a very delicate and pleasing colour; Faithful, pale sulphur yellow, a very fine flower of refined colouring; Gipsy Queen, dark crimson; Gladys, yellow suffused cinnamon; Hope, soft pinky mauve; Iliad, creamy buff suffused salmon, a very fine large flower; Juliet, salmon buff, suffused yellow; Liberty, scarlet crimson; Martial, brilliant scarlet; Old Gold, deep golden amber; Oriana, pure rose; Peggy, a lovely shade of pure yellow; Radium, bright scarlet; Salute, deep blood red; Scarlet King, bright orange scarlet; Toreador, scarlet; and White Lady, a fine white self.

THE CHARMS.

These are sometimes called miniature peony-flowered dahlias, but "Charms" is a more appropriate name, and it is now becoming more generally used. They are all that the name signifies, being charming for home decoration and equally beautiful in the garden. This type has revolutionised the decorative dahlia, being unsurpassed for beauty of colour, freedom of

Digitized by Google

flowering, and they give brilliant colour effects that are unobtainable from any other autumn flower.

Some of the finest varieties are Charmer, shades of orange chestnut and orange salmon; Dennys, intense orange scarlet self; Mac, a lovely salmon rose on a yellow ground; Peach, rose suffused lemon with a wire edge of crimson; Amos, a wonderful shade of rich scarlet crimson; Crimson Glow, deep crimson; Dazzle, brilliant scarlet; Elegance, soft silvery rose; Fusee, a beautiful shade of rosy salmon on a yellow ground; Gladys Unwin, soft pink with lemon yellow base; Jess, orange suffused scarlet; Little Edie, a beautiful shade of shrimp pink; Norah Bell, pure cerise on a yellow ground, almost like the colour of the cottage; Our Annie, shrimp pink on a yellow ground; Picture, a blend of orange flame and chestnut, a distinct and attractive colour; Rosie, a soft shade of deep rose; and The General, madder crimson.

THE DECORATIVE TYPES.

These include two sections, the large and the small flowered decorative dahlias.

In the former the following are all varieties of merit: Aristocrat, cream, lightly suffused salmon, a beautiful flower of delicate colouring; Christine, chrome yellow; Emblem, rose pink, very strong stems; Mirth, salmon mauve changing to pale rose; Cambria, rich pink with white centre; Fireman, fiery scarlet; Mrs. Courtney Page, creamy rose shaded salmon; Nancy, a lovely shade of almond blossom pink; Psyche, deep chrome yellow self, large flowers on very strong stems; Romney, maroon crimson with blackish centre.

The small-flowered sorts are nearly as useful as the charms. The following are some of the best varieties: Carine, a magnificent orange-scarlet self; Raider, cinnamon with chrome base; Tipsy, a brilliant scarlet self; Aglaia, orange fawn overlaid salmon, very beautiful in artificial light; Feodora, cerise salmon with lemon base; Mrs. F. J. Sage, a brilliant scarlet red; Rhoda, orange rose passing to shrimp, curling florets; Thursa, a distinct shade of madder red; and Velma, bright rose on yellow base.

SINGLE DAHLIAS.

These include the mignon type, of which the popular Coltness Gem is a well known example, and the Parisian singles, of which Crawley Beauty is a type. The latter have longer and more loosely arranged florets than the ordinary singles.

Clematis, rosy lavender, which has flowers resembling the clematis; and White Tip, a flat flower of distinct shape with a light, graceful habit and deep crimson flowers tipped with white, are two other useful singles.

THE STAR DAHLIAS.

This is a well known and very popular type, being much used for garden decoration or cut flowers. They have a good, bushy habit, attaining a height of from 3ft. to 4ft., and the semi-double flowers are freely produced on long, wiry stems. Crawley Star, White Star, Crimson Star, Coral Star, Reigate Star and Yellow Star are all beautiful varieties.

POMPONS.

Owing to their somewhat formal character these are not popular, and are mainly used for exhibition. Good varieties for this purpose are Amelia, pale pink with white centre; Glow, orange; Gannymede, fawn; and Ideal, clear yellow.

DOBBIE'S BEDDER.

This is a camellia-flowered variety of pale yellow colouring and very floriferous, which is admirable for massing in large beds. It is extensively used in public parks.

NORMAN LAMBERT.

SOME FLOWERING BARBERRIES

AMONG our spring-flowering shrubs the members of the genus berberis are not the least important. Most of the species look well when laden with golden blossom. At first sight the inflorescences of the different species seem to be rather similar, but if one looks at them more closely one is surprised by the many variations in their structure, as well as in the individual flowers. The flowers are mostly arranged in more or less elongated racemes, but in a number of species the inflorescences are reduced to one or a few fasciculate flowers, while in others the inflorescences become paniculate. The last type shows an extraordinary development in a group of South American species which at present are almost wholly absent from our gardens.

The best known type of species with solitary flowers or few flowered fascicles is B. Thunbergii. I did not know its real beauty until I saw it around Boston in Massachusetts. In the Arnold Arboretum and in the public and private gardens of Boston and its vicinity it is not only a common but a very handsome shrub. When flowering in spring we enjoy the somewhat pale yellow of its flowers, which is delicately suffused with red. It is, however, at its best in the autumn with its richly tinted leaves and its bright red fruits. There are a few varieties; one is called var. Maximowiczii, which hardly differs from the type at all. A dwarf compact form is var. minor, and a very similar, if not identical, one var. Dawsonii. The so-called var. pluriflora is mostly B. ottawensis, a hybrid between B. Thunbergii and B. vulgaris of which I have seen different forms in American as well as in European gardens. There may exist a form of the true Thunbergii with somewhat racemose inflorescences, but, after all, it may be of hybrid origin, representing a form of B. ottawensis that comes very near the Japanese parent. B. ottawensis ought to be propagated freely, because it seems to be a shrub of great merit for our gardens. Other species with few flowered inflorescences are B. diaphana from northern and central China, and B. yunnanensis from south-western China. The individual flowers

B. AMURENSIS, ONE OF THE FIRST TO FLOWER.

THE GRACEFUL INFLORESCENCES OF B. ARISTATA.

Digitized by Google

of both are much larger than those of B. Thunbergii, and of a clear yellow without any reddish hue. The berries, too, are larger. The leaves of both these species show a beautiful crimson colouring in fall. Like their Japanese cousin, they form rather dense round bushes.

Of the species with true simple racemes, B. vulgaris is the well known type. Very closely related to it are two species of eastern Asia, B. amurensis and B. Regeliana. All three species look much alike, and it is hardly possible to state the differences. Of the last species which is a native of Japan, the leaves are of somewhat firmer texture than those of B. vulgaris and its relative from the Amurland. The serration, too, of the leaves of B. Regeliana is finer and closer. B. amurensis is usually the first one to sprout and to flower in spring, as is the case with so many other woody plants from this region. In autumn it seems the finest of the three when covered with its berries. There are, however, in our gardens quite a few hybrids, of which one or the other of these species is a parent, or even hybrids between vulgaris and either amurensis or Regeliana. It is, therefore, rather difficult to establish the true forms. Our illustrations show flowering parts of the two Asiatic barberries.

B. REGELIANA, SIMILAR IN APPEARANCE TO THE COMMON BARBERRY.

A very interesting and valuable species with racemose inflorescences of which I can show the flowers, too, is B. aristata from the central Himalayas. It was probably introduced by Wallich at least a hundred years ago. At about the same time, in 1820, another species came to England from Nepal, which has been confused wth aristata. It was first pictured under this name by Ker in 1823 in the Botanical Register. Ker took it for B. aristata of De Candolle, but the plant figured is B. chitria of Hamilton. The latter is an entirely different plant, and probably has to be put in a different section on account of its paniculate inflorescences. I am surprised that such an acute observer as Mr. Bean still keeps B. chitria as a variety of B. aristata. This species belongs to a section I have called Tinctoriæ, of which several forms are found in the Himalayas.

Of B. chitria I saw an extremely fine large specimen in the gardens of the R.H.S. at Wisley. It is one of the most beautiful barberries when in flower, the handsomest of the deciduous ones. The panicles reach a length of more than 8ins. I do not know whether it fruits freely. It does not seem to be quite as hardy as aristata, of which I have seen several old specimens in the gardens of western and central Europe. B. aristata is not quite as showy when in flower; the fruits are of a rather dull, plum red colour when fully ripe, covered with a faint bluish white bloom. I regard B. aristata as a good garden plant, but there are some hybrids of which it is one of the parents that are certainly of a greater ornamental value.

Another species I wish to mention is B. Gilgiana, a member of a section rather distinct by the shape of the inflorescence as well as by the pubescence of the leaves, a character very seldom observed among the barberries. This species from northern China and those related to it from the same region are still almost unknown in cultivation. I had an opportunity to study B. Gilgiana, B. brachypoda and B. Giraldiana in the Arnold Arboretum. B. brachypoda is the best known of them. B. Giraldiana had been raised from seeds sent by Père Giraldi from Shensi, and had been distributed by the well known nursery of H. A. Nesse, at Weener, Germany; but it is not mentioned in his latest catalogue.

One of the finest of the barberries that came into cultivation within the last decade is B. vernæ, which was mentioned in THE GARDEN a week or two back. CAMILLO SCHNEIDER.

NOTES OF THE WEEK

SHORTIA GALACIFOLIA.

THE late E. C. Buxton grew many plants well, but he excelled with this shortia. A few days ago I had a look at them. All were just about to break bud, the season being very early, and such vigour and development as theirs must be uncommon in this country. In the first place, the leaves are so large that they could scarcely be distinguished from those of Galax aphylla, which grows among them. The stout, rambling branches of the plants flop about the rocks, covering their mossy crowns, and they filled in the spaces between with dense masses of healthful foliage. One secret of this striking success is doubtless the selection of the right spot in the first instance. The site is cool, partly shaded, and it is never really dry or really wet. The mountain atmosphere of Bettws-y-Coed probably also helps. But Mr. Buxton always held the opinion that pine-needle leaf-mould was the food for shortias, and this he provided, with a certain amount of peat. But the plants for many years have enjoyed a natural fall of pine-needles from a small Pinus montana which stands over them, and a large Douglas fir and other conifers close by. They are, in fact, at practically any season always more or less sprinkled with these leaves, and it is into the loose, friable residue of the latter that they root as they spread about. In our own garden shortias are given a similar fare, and they certainly seem to thrive on it, but we have not yet managed to inspire them with the amazing vigour of the Bettws-y-Coed plants. —A. T. JOHNSON.

A SHOWY ROCK [illegible]DEN OR BORDER PLANT, ANCHUSA MYOSOTIDIFLORA.

ANCHUSA MYOSOTIDIFLORA.

THERE appears to be a diversity of opinion regarding the subject of this note. Farrer consigns it to cool, shady and undesirable corners, while one catalogue says it is good for a rough corner, and a plant which has not lived up to its reputation. However, I am going to say a few words in its favour. It can, perhaps, be described as a very fine

Digitized by Google

CISTUS LORETI, A NEAT SHRUB FOR THE ROCK GARDEN.

forget-me-not, and the illustration, taken early in March, 1926, gives a good idea of what the plant is like. It is not really a rampant grower and at this period of the year a clump of its light flowers are very showy on the rock garden or in the border; the plant attaining a height of about a foot. This pretty plant is a native of Siberia, from whence it was introduced a century ago. It is increased by seeds and division, and is sometimes known under the name of Myosotis macrophylla.—T. W. B.

OMPHALODES LINIFOLIA AND GERANIUM LANCASTRIENSE.

THIS little picture illustrates the method adopted at Gravetye Manor of growing alpine and other choice flowers in retaining walls. It is also a pretty example of the charming results arising from this much abused form of gardening. The plant in the foreground is Geranium lancastriense, which hails from a little island near the county of that name. It is a beautiful plant, and, in addition to its value in the rock garden, forms lovely edgings to beds of other flowers, and in October the plants are covered with pretty soft rose-coloured blossoms each 1¼ins. across and finely marked with dark lines. In the rear is that delightful hardy annual from Portugal, Omphalodes linifolia, which grows about 18ins. in height, and arising out of its grey-blue glaucous foliage are numbers of elegant branching spikes of the most lovely white forget-me-not like flowers faintly suffused with blue and delightful for cutting. This is one of our most graceful annuals, the flower sprays so thin and yet wiry as to withstand any storm without support of any kind. The seeds may be sown either in spring or autumn, the latter for preference, as the resulting growth is much stronger and the plants more effective. Once established this annual flower reproduces itself if allowed to remain in the same place, for which reason it is a very desirable plant to associate with alpine flowers. Between the two groups mentioned above will be seen Erysimum linifolium, a little wallflower-like plant with spikes of pretty lavender or mauve-coloured flowers. The seeds are scattered where the plants are to grow about the end of July each year, and thus we get the flowers during May and June.

Not the least important part of this little picture is the stone itself, which is quarried on the estate and very plentiful and, as will be seen, weathers beautifully, lichens in masses of various shades of grey and green forming a mantle of tender colouring over the exposed parts in quite a short time, and this, associated with plants in bloom, often reaches the ideal of beauty. The wall was not built without reason, as in the first place a loose bank 4ft. in height had to be supported, and therefore it serves a very necessary purpose. The stones are cut by the men on the place to a uniform thickness, and as each layer is put down, are tilted slightly inwards and the plants laid along the surface of each layer of stone as the work proceeds. Little or no soil is used between the layers, and this is a very important point, for half the wall gardening we see to-day is ruined by the cramming of large quantities of loose soil between the stones, which during times of drought and frost crumbles away exposing the roots of the plants. The plants here shown get their nourishment from the bank of earth in their rear, and to increase the supply of moisture each layer of stone is set back 1½ins. beyond the face of the preceding layer. Gentians flourish and bloom profusely when grown in this manner.—E. MARKHAM.

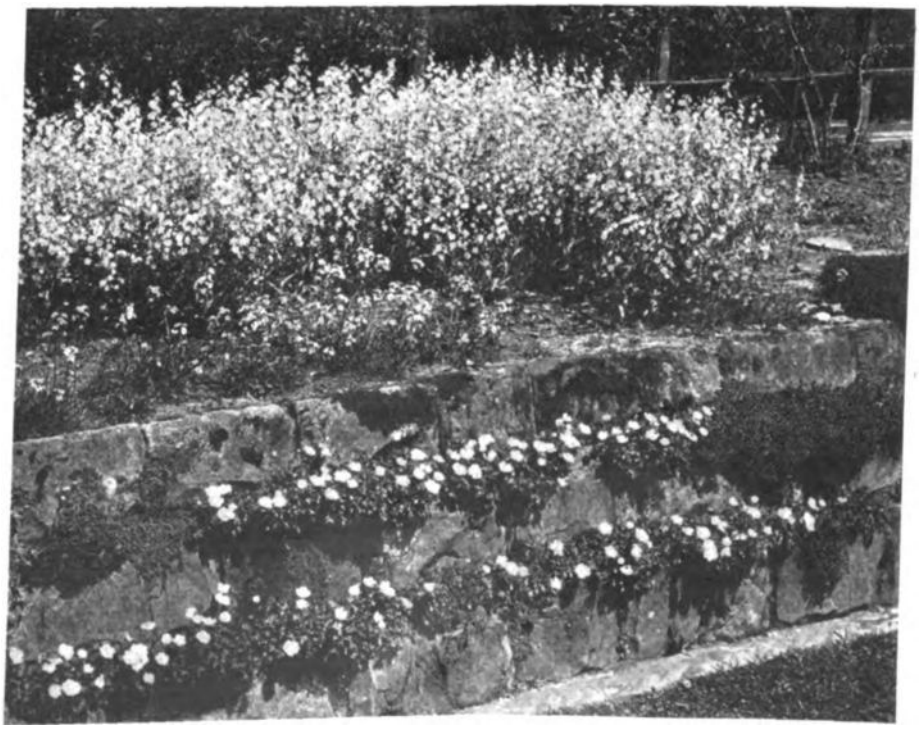
TWO GOOD ROCK ROSES.

Cistus ladaniferus and C. Loreti.

AMONG the taller rock roses C. ladaniferus is perhaps the most beautiful, it being unequalled in the elegance of its habit, and none can rival it in the size and delicate texture of its flowers. The latter, borne singly at the axils of the long, narrow leaves, are often 4ins. across, and each pure white petal has at its base a bold blood-crimson blotch. If not the hardiest of its race, C. ladaniferus will withstand 20° of frost in a light, well drained, stony soil. It is a fast grower, soon making a bush 5ft. high and as much through, but greater heights are by no means uncommon in our milder counties. Still, this species, like many others of its genus, is not long lived, and a few young plants, which are easily raised from seed or cuttings, should always be kept coming on.

The unblotched form of C. ladaniferus known as var. immaculatus (albiflorus) is, to my mind, even more beautiful than the type, and if ever I were condemned to grow but one rock rose, I think this would be my choice. Its blooms are not only very large, 5ins. and sometimes more in width, but the pure white, papery petals are exquisitely crimped.

C. Loreti (a ladaniferus × monspeliensis hybrid) is a most delightful rock rose for the rock garden, its compact habit, low stature (about 3ft.), ample foliage of a cheerful green, and large and abundant flowers together making a most engaging little bush. The blossoms, which are rather more than 2ins. across, are borne singly or in small clusters; they are white with a rosy carmine blotch, and it is noteworthy that they last longer than those of most cistuses, often till the next morning. This is one of the hardiest of the rock roses, frequently being quite uninjured by frost, which has killed many of its kindred. It is readily increased by cuttings in August. Syn. C. lusitanicus.—A. T. JOHNSON.



AN EXCELLENT METHOD OF GROWING ALPINE AND OTHER CHOICE FLOWERS.

Digitized by Google

AGAPANTHUS UMBELLATUS.

A Plant for Tubs or a Warm Border.

THIS is a half-hardy plant coming from the Cape of Good Hope. It has been for many years a favourite in our gardens, succeeding well outside in our southern counties throughout the year when our winters are mild. It has, however, been regarded mainly as a greenhouse subject, and it is a very charming one, too, when properly treated. Usually, the specimens are giants, growing partly out of big cracked flower-pots as the plants produce roots freely in any good soil. There is a use, however, for large plants in fairly large gardens, as they look well in recesses on lawns and at the sides of broad paths; but they are not so attractive in small gardens, unless the plants are smaller, too. I strongly recommend these small plants both for gardens and greenhouses, as they flower just as freely when the pots begin to fill with roots. Every two or three years the plants should be reduced by division and the number increased in this way. Small specimens look splendid as dot plants in the summer flower beds; they flower from August to early in October and produce quite long flower stems—2ft. to 4ft. high. —G. G.

A FINE ALPINE FROM NEW ZEALAND.

Tratia linnæoides (*syn. Lobelia linnæoides*).

IT may be that Tratia linnæoides is not so well known as one or two other members of the genus, or it may be that some have found it more difficult of cultivation; but, whatever the reason, it is certain that this valuable plant is not so much grown as it deserves to be. This gem hails from New Zealand and is not difficult to propagate. It can be increased from cuttings taken at the end of July and inserted in a very sandy compost in the hardy cutting frame, taking care to pot up the cuttings as soon as rooted. If grown in a pan in the alpine house it will soon spread to fill the pan, and in the autumn can be tapped out and divided. It comes into bloom about the end of July or the beginning of August, when numerous flowers are produced on very slender stems about 3ins. or 4ins. long. The flowers are almost pure white, though at times, in the young stage, there is a faint tinge of blue which seems to become more pronounced as the blooms get older.

The leaves, which are small and round, arise along the creeping stems in pairs. What it most enjoys on the rockery is a position where it can get a fair share of both sun and shade and a good soil in which peat and sand are present.—W. H.

A CHARMING WINDFLOWER.

Anemone Seemannii.

WINDFLOWERS of the character of our lovely wood anemone are always favourites and, whether in the border, the rock garden or naturalised, receive the unstinted admiration of most flower-lovers. There are few species or varieties which do not deserve our favour, and a collection of windflowers of this type is full of delight to those who possess it. Yet few of them can hope to oust our wild Anemone nemorosa, and its influence in the creation of A. Seemannii, a hybrid between it and A. ranunculoides, has given us a plant of much, though quiet beauty. The union has produced a plant almost intermediate between the parents, its size of foliage and flower showing the influence of A. nemorosa by having its leaves and flowers larger than those of A. ranunculoides, but that of the latter in the colour of its pretty flowers, which are of a pleasant shade of straw yellow. This hybrid has been raised in more than one quarter, and is even found as a natural hybrid in some woods where the two parents grow wild. It is in commerce, though not frequently offered, and I see it in the list of Mr. Van Tubergen of last season. It first came under my notice through being sent me by a Danish correspondent twenty years ago, and so pleased was I with this little hybrid that I have never lost sight of it since then. It flourishes wherever A. nemorosa or A. ranunculoides do well.—S. ARNOTT.

THE HARDINESS OF GEUMS.

I MUST confess that, grown under normal conditions—that is to say, in the herbaceous border—I have found Geum Mrs. Bradshaw a fractious person to deal with. Recently, however, I have come to the conclusion she suffers a good deal from sore throat, especially if given rich soil. My soil is very light, sandy loam, and a good deal of old manure has been added to the herbaceous border. Lady Stratheden thrives exceedingly well, being one of the first and one of the last plants to flower. Mrs. Bradshaw looks thoroughly unwholesome, and like a hypochondriac, draws all possible attention to herself by lifting pathetic, semi-rotten crowns out of the ground for my inspection, and spreading an invalid's shawl of decaying leaves round about her. So much for the border plants.

On the lower slopes of the rock garden she is happier, but I am not at all sure she appreciates the autumn mulch of old manure and leaf-mould she shares with the rock plants. On the higher slopes, where she is perched 6ft. up, with a drop so sudden that moisture drains away quickly, and where I never climb to give her manure, she is as vigorous as is Lady Stratheden in the border. These particular high grown plants are at least four years old, and to-day they form large, flourishing clumps of handsome foliage, with upstanding flower stems showing promise of profuse bloom.

I am experimenting with seedlings in the border. These have a plentiful admixture of sharp sand with the soil about their roots, and solid collars of sand about their susceptible throats.—GWENDOLYN ANLEY.

SHRUBS FOR WALLS

BY W. J. BEAN.

(*Continued from page* 233.)

A GOOD many of the Australasian daisy bushes (OLEARIA) can be grown on walls, but comparatively few have much beauty of flower, although a goodly number are handsome enough in leaf. Near London the best perhaps for blossom is O. macrodonta, but even with wall protection it is a poor shadow of the plants covered with large trusses of white flowers one sees in the gardens of mid-Sussex and farther southwards and westwards. The beautiful O. semidentata, whose flowers are 2ins. to 2½ins. wide, with purple ray florets and a darker disc, is worth trying at the foot of a wall. As having more beauty of leaf than of flower the following may be mentioned: OO. argophylla, Forsteri, furfuracea, nitida and Traversii.

O. albida and O. myrsinoides are nearly hardy at Kew and the latter especially produces its white flowers with great freedom. O. Solandri, with long, slender, broom-like branches and heath-like leaves, is elegant, the whole shrub having a yellowish tone due to the down on the young shoots and beneath the leaves, also to the outer bracts of the flower-heads being of that colour.

OSTEOMELES.—There are two kinds of osteomeles in cultivation—O. Schwerinæ and its variety microphylla—which (certainly the species itself) seem to need a wall for their successful cultivation, and are worth it. They have small, pinnate leaves, pure white flowers ½in. wide and blue-black fruits. The type makes long, graceful, slender shoots which blossom in June. The var. microphylla, which Wilson introduced from the Min River valley in Western China in 1908, is a closer, neater grower with tiny leaflets only one-twelfth to one-sixth of an inch long. It has borne large crops of its small white flowers and egg-shaped purplish fruits on an east wall at Kew. It is suitable for filling a vacant place 4ft. or 5ft. high.

PENTSTEMON.—Several of the Californian shrubby and sub-shrubby pentstemons are very showy in flower and a few species are well deserving of a place on a sunny wall, a space up to 3ft. or 4ft. high being sufficient for them. They all have the typical funnel-shaped flower of the genus and the following may be recommended: PP. cordifolius, flowers scarlet; corymbosus, bright red; heterophyllus, reddish purple. They flower from late June onwards.

PHLOMIS FRUTICOSA.—With its foliage like that of a giant sage, and its bright yellow stalkless flowers clustered in their axils, this shrubby labiate (often called "Jerusalem Sage") is an interesting plant that flowers over a considerable length of time in autumn. It is a sun lover.

PHYGELIUS CAPENSIS.—In the milder parts of the country this South African shrub is grown fully in the open and is very handsome, with its terminal panicles 1ft. or so high, stiffly erect, but with the scarlet tubular flowers, each about 1in. to 1½ins. long, pendulous. Near London it needs wall protection. It grows 7ft. or 8ft. high.

PILEOSTEGIA VIBURNOIDES.—Although known to botanists as an Indian plant for many years, this climber appears to have first reached this country from China, whence Wilson introduced it in 1908. It is the only species in the genus, and is an evergreen with dark green, rather leathery leaves up to 5ins. or 6ins. long. The flowers are creamy white, densely crowded in a terminal pyramidal panicle 4ins. to 6ins. across. Each flower is ¼in. to ⅓in. wide, with four or five petals, conspicuous stamens and opens in September. Closely related to the hydrangeas, it promises to make a pleasant addition to

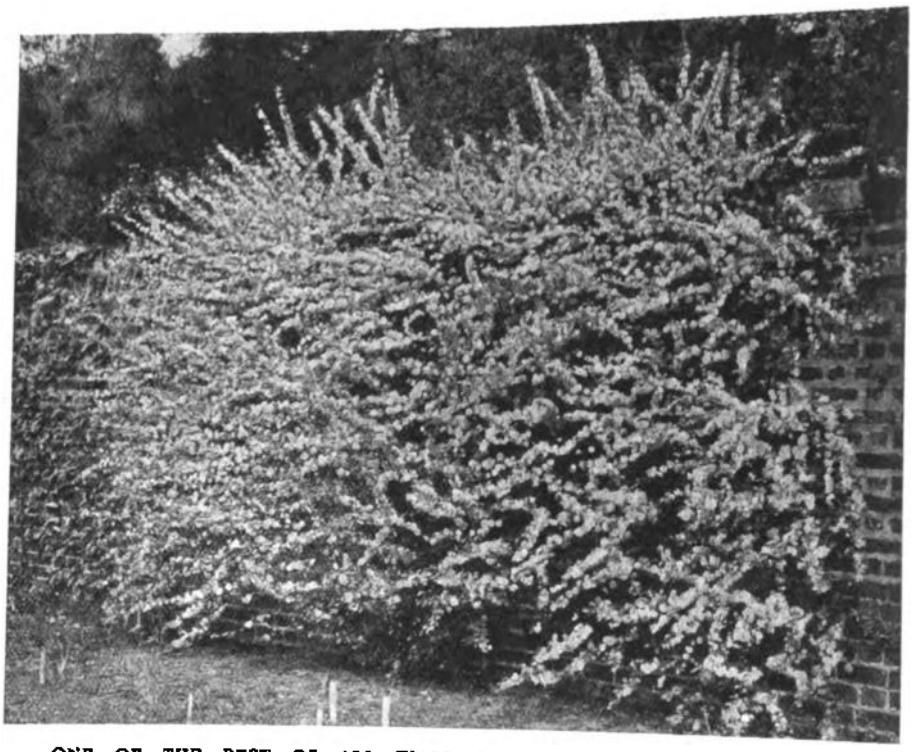
Digitized by Google

evergreen wall plants. Wilson gives its maximum height as 22ft. It has succeeded very well at Aldenham.

PITTOSPORUM. — Of this extensive genus very few are hardy away from the milder localities and few in my opinion are worth wall space. P. crassifolium has for many years been grown on a wall at Kew and covers its space densely with the dark evergreen foliage, but rarely flowers. P. Tobira, the Japanese species, also evergreen, has charmingly fragrant, creamy white flowers in clusters, 2ins. or 3ins. wide. One of the best of all variegated shrubs as one sees it in the gardens of the south-west, is P. eugenioides variegata, but I have not seen it tried on a wall. Its variegation is peculiarly pure and clean-looking.

PRUNUS.—Nearly all the members of this very extensive genus are, of course, among the very hardiest of trees and shrubs, but P. ilicifolia, a Californian evergreen of the cherry laurel group, must be given wall protection. It has small, white flowers in short racemes and shining, conspicuously toothed leaves. A curious and interesting species of the almond group is P. orientalis, with silvery grey foliage; this, too, needs a wall and as much sun as it can get. But by far the finest of all prunuses for walls is the double-flowered form of P. triloba, one of the most beautiful indeed of all wall shrubs. The individual flower is 1½ins. wide, delicate rose, composed of many petals. Its flowers appear in March and April and the blossoming shoots should be pruned back almost to the old wood as soon as they are over. This gives the shrub a full season to make a new crop of shoots, which will grow 1ft. to 2ft. long before the summer is over and flower in their turn the following spring. For very many years a plant on a wall at Kew, covering a space 15ft. by 8ft., made a glorious display until it was destroyed by the silver leaf disease.

PUNICA GRANATUM.—The pomegranate is nearly hardy and in a sheltered corner outside the temperate house at Kew has stood uninjured and borne flowers and fruit for some years past. Possibly a really hard winter would be too much for it. For wall cultivation the double-flowered variety, with its fine bright red flowers, 1in. to 1½ins. wide, is better than the type; and for a low space, say 3ft. or 4ft. high, the charming dwarf var. nana should be selected. They flower from June onwards and love the sun.



ONE OF THE BEST OF ALL WALL SHRUBS. PRUNUS TRILOBA FL. PL.

PYRACANTHA.—All the pyracanthas as yet introduced are perfectly hardy, with the exception of P. angustifolia, which must have wall cultivation. The common one, P. coccinea (especially its var. Lalandei), flowers so freely and bears such magnificent crops of its brilliant red fruits in the open ground that it need not be given wall space if that be scarce. At the same time, for a sunny house front it would be difficult to find an evergreen more admirable. It is still, I consider, the best of the genus, but it does not retain its berries so long as either P. Gibbsii or P. yunnanensis. The latter, with its profuse crops of orange red fruits is a good wall shrub, but P. Gibbsii is so vigorous and so hardy that it is better in the open. It is really a small tree at Aldenham. Both have smaller fruits than coccinea, and they remain on the branches well into the New Year, as they do also on the yellow-fruited P. angustifolia. In general appearance, P. Rogersiana, with its small leaves, is the most elegant of the pyracanthas, and its fruits vary in colour from yellow to orange red, but I have never seen very large crops on it.

RAPHIOLEPIS. — The commonest species of this genus, R. japonica, seems to be quite hardy in the London district. The newer R. Delacouri, also, is growing well in the open, although it has not yet been put to a very severe test and may eventually prove to be only really safe on a wall. If so, it will well deserve it as a pleasing evergreen producing its clusters of charming rosy pink blossoms at almost all seasons and not needing much room.

RHUS TOXICODENDRON (Poison Ivy).—So evil are the effects of the sap of this plant on the skin of many persons—producing painful and unsightly eruptions, that take long to cure and occasionally recur—that it is better kept out of the garden altogether. There are two forms of it, one a spreading bush, the other a climber, the trifoliate leaves of both of which turn a beautiful red in autumn. They are only mentioned here by way of warning, not of recommendation.

PYRACANTHA GIBBSII. A MOST ORNAMENTAL PLANT FOR WALL DECORATION.

(To be continued.)

IDEAL FORM in the MODERN GLADIOLUS

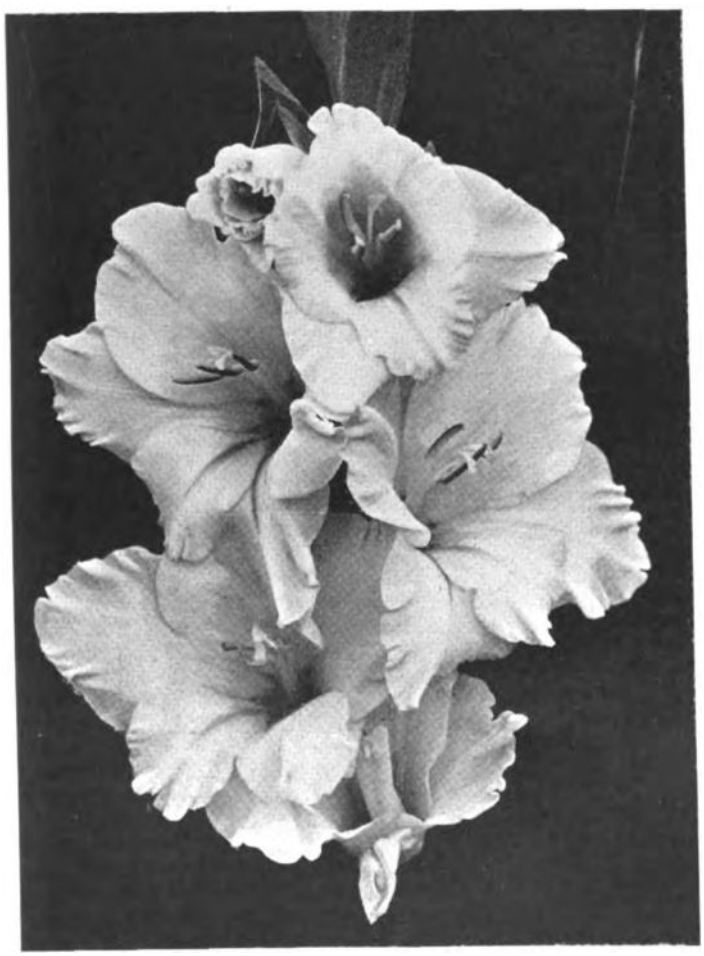
IN many popular flowers, there is a recognised ideal, a generally-accepted standard (or standards) by which the merit of the different varieties of those flowers may be judged, but to the individual, ideal form or type in any flower must always be that which most completely satisfies personal taste and requirements.

The purposes for which a flower is intended have a decided bearing upon how its merit should be ascertained. From the point of view of the exhibitor some varieties of roses would be hopeless, yet as bedders they may be superb. We find in many flowers the distinction made between "exhibition" varieties and "bedding" (or "decorative") kinds, and it must be said that the latter of late years has, in most instances, become the more popular type. Roses and dahlias furnish good examples of this, and although I would never belittle the undoubted influence for the better which the exhibitor exerts, he is, after all, greatly in the minority. I believe hybridists and raisers, generally, are fully alive to this tendency in public taste, and are the less likely to condemn a variety lacking in exhibition "points" provided it is pleasing to the eye.

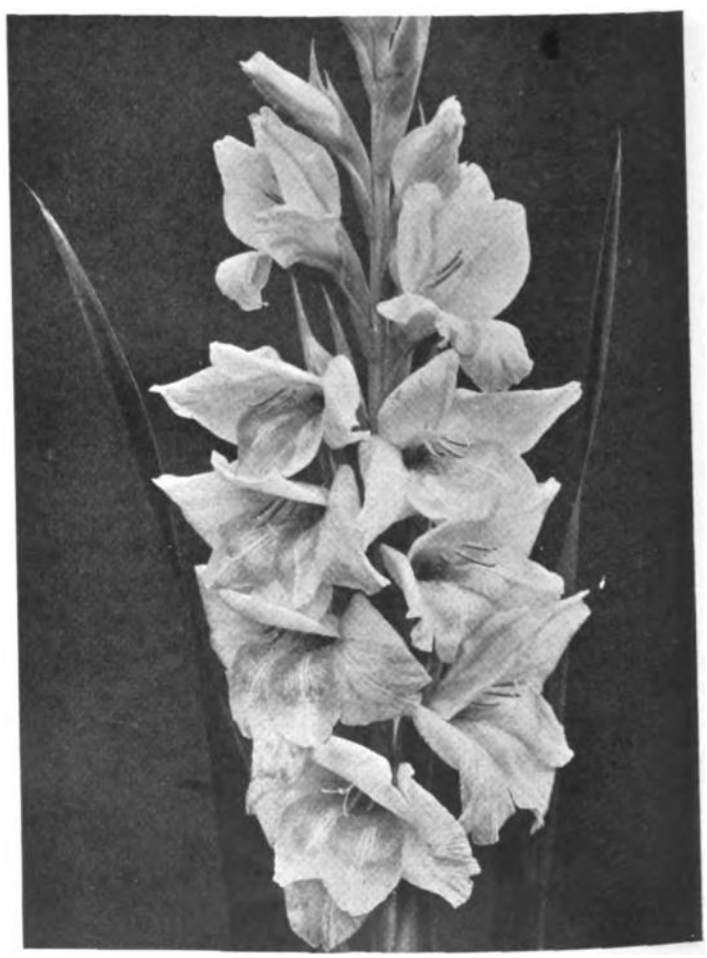
It is exceedingly difficult, perhaps impossible, for any one individual to lay down hard and fast rules as to what might be considered good form in modern gladioli. Personal taste is given a much wider scope than in the case of most other flowers on account of the divergence of form and habit. Even the two divisions known as large-flowering varieties and primulinus hybrids, are being bridged by some of the comparatively large-flowered primulinus hybrids, and the distinction between the two classes is, in some instances, very small indeed. It is, of course, not surprising that present-day gladioli present such a wide divergence in form, for their ancestors comprise a large number of distinct species. "J. C." in a very interesting article in THE GARDEN of March 6th, 1926, gave details of the four distinct types (gandavensis, Lemoinei, nanceianus and Childsii), themselves raised by crossing and inter-crossing various species, which are the parents of present-day large-flowering varieties. The primulinus hybrids came later, and are the result of crossing the large kinds with G. primulinus.

In giving my personal views on what is good form, I will deal with the large-flowering section first. I do hope the increasing interest now being taken in gladioli may not make some of us hypercritical or give us fixed hide-bound ideas on this question of "ideal form." We must remember we are not dealing with a flower of the nature, or the limitations in form, of such subjects as carnations, sweet peas, violas, etc., and just those points of size, shape and placement of blooms in gladioli which may be condemned as faults by some, might appeal to others. A few days ago, I asked a friend—a gladiolus enthusiast who in the past has exhibited them very successfully—if he had an ideal or a definite standard by which he arrived at the merit of any variety for his particular purpose. He said "Yes" and rather astonished me by asserting that, judged by his standard, he perceived little or no improvement among varieties of to-day as compared with those of a quarter of a century ago. Be that as it may, I was surprised to find that his standard of perfection (an exhibitor's point of view), was almost identical with my own, for with me, their decorative value is everything. Apart from colour, these are the points which appealed to us both:

FLOWERS.—Large and wide open, with rounded petals. General outline inclined more to the form of a circle than triangular. Petals of good substance and the larger number of florets open on the spike at the same time, the better.



1.—A good large-flowered gladiolus with plenty of substance in the petals.



2.—A spike of rather loose habit with too much stem showing, but with a large number of flowers out at one time.

Digitized by Google

The spike itself should be long and straight and the placement of florets regular, all running more or less in one way, not with the two sides facing in nearly opposite directions and showing an expanse of stem in the middle, nor yet sticking out at all angles in an irregular kind of way. The florets should not be crowded as though they each find it difficult to expand fully without covering their immediate neighbours, neither should there be noticeable looseness in the fully open spike. To make these points clear, shall we just judge the two spikes illustrated (No. 1 and No. 2) by this standard, finding out their defects and their good qualities. May I request my reader to turn back to page 159 of the March 13th number, which also shows two spikes to which I will refer by their names, Purple Glory and Orange Glory.

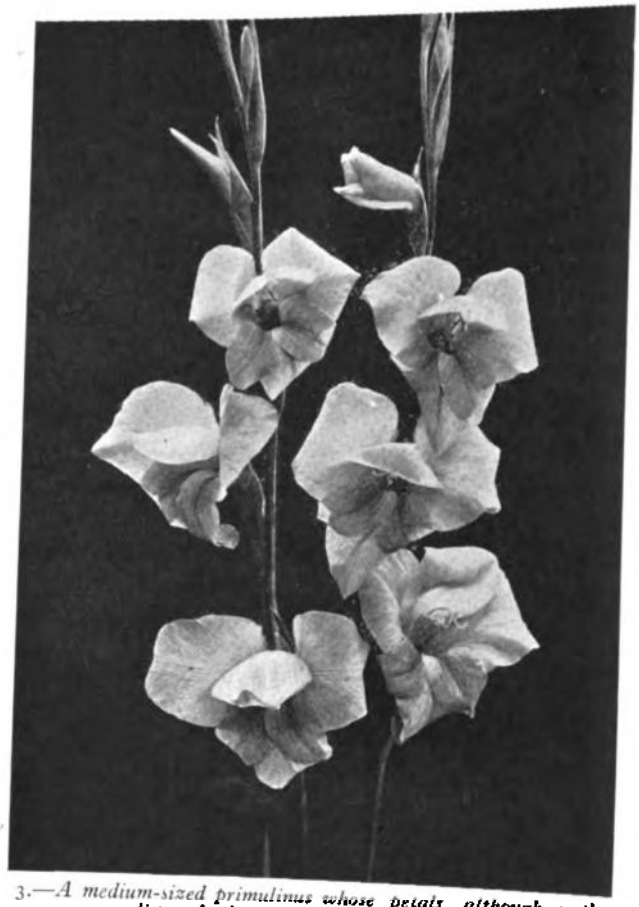
No. 1.—*Defects:* Florets rather too crowded on the spike and not nearly enough open at once. Very slightly tubular in form. *Assets:* Fairly large flowered with plenty of substance in the petals (which are ruffled or crimped).

No. 2.—*Defects:* Florets a little on the small side, very tubular, with top petal almost hooded. Petals too pointed and too "thin." Very lacking in substance, which causes a curl on some of them approaching the twisting of the skin peeled off a tomato. Owing to the tubular shape of florets, the whole spike appears "loose" and too much stem is shown, particularly towards the top. *Assets:* A large number of florets open at the same time.

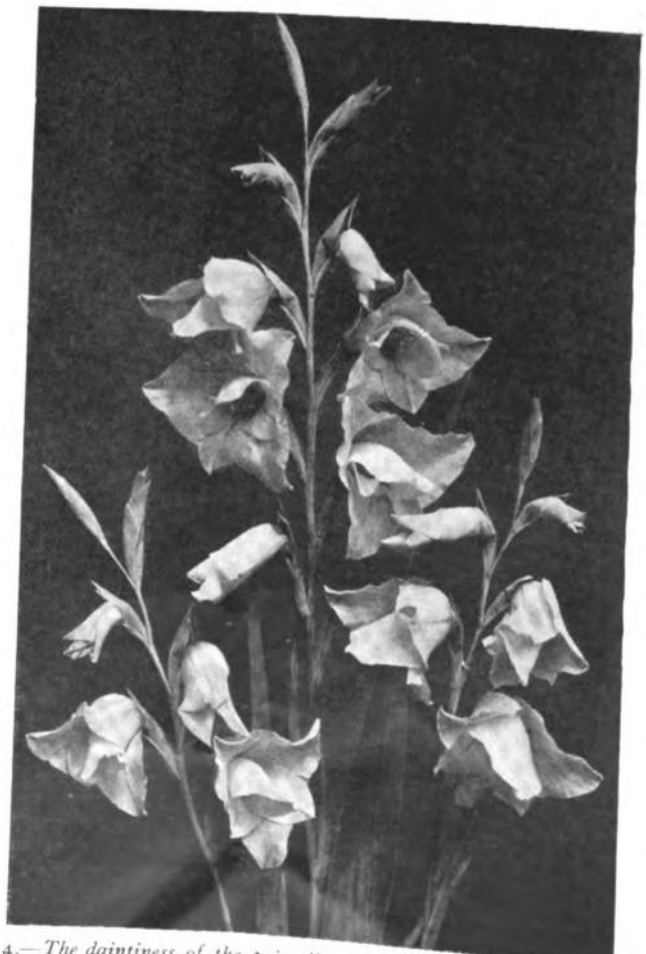
If we turn back to page 159, much better spikes are given. The only defect from my point of view in Purple Glory is that the second bloom from the bottom on the right-hand side is slightly misplaced (a fault easily remedied by an exhibitor). The shape of the flowers and the texture of petals obviously are excellent. They are wide open (just glance again at No. 2 and note the great difference). Each individual petal is well rounded and the outline of each floret circular rather than triangular. Perhaps a keen exhibitor might say that not enough flowers are open, but for all that, it is a very handsome, well made spike and easily the best of the four we are discussing. Orange Glory, too, is a nice spike, large, wide open, rounded blooms, with plenty of substance, but their placement is just a wee bit crowded. I should place it second, for it is certainly far ahead of both No. 1 and No. 2.

This sums up my personal opinion of good form. Many of the most popular and valuable of all varieties would fall short of it, or indeed, any similar attempt. Take the case of Red Emperor; here we have a variety which never fails to invoke admiration if half a dozen or so spikes are nicely arranged in a large vase, bowl or basket. No one would wish to dispense with it, yet judging by the above standard, apart from colour and size of flower, there is apparently little to recommend it; from a decorative point of view, one would rate it higher in value than some other deep red varieties which would conform more nearly to the suggested exhibition standard. Then there are the closely-knit, well made and compact spikes, typical of many of the Dutch introductions and the fairly wide spaced, curiously reflexed petals shown in the American gladiolus Dr. W. Van Fleet. One could mention other distinct forms, every one of them very beautiful and each making its separate appeal. I feel confident the frilled or ruffled petal has come to stay; it may not be such a vast improvement as was the "frilled" type in sweet peas, or so quickly take precedence over the plain flower, but it is a step in the right direction and in my opinion tends to make a very charming flower still more beautiful. Judging by personal experience, if we leave out the question of colour entirely, I think the Purple Glory form is nearer the average taste than other types of large-flowering gladioli.

Primulinus hybrids differ so much in size, shape and placement on the spike, that ideal form is even more largely a question of individual taste than in the large-flowering varieties. Prims. are less formal, much daintier and more graceful, generally speaking, and their value is confined to a greater extent to their purely decorative qualities, particularly for indoor work. I feel sure *one should judge them entirely from the decorative standpoint.* Perhaps it will be a good plan to enumerate those points which are inartistic or likely to detract from the lightness and gracefulness of the flower. Too thick and fleshy a stem, quite out of proportion to the size of the bloom, is the fault of a few varieties. Nydia being a good example, although small corms of Nydia will often produce a spike in which the fault is modified. The characteristic hooded upper petal of primulinus species is sometimes slightly exaggerated in the hybrids. Personally, I do not wish to see this rather refined hood disappear, but if the droop is so pronounced as to hide the stamens and pistil in a spike held on a level with one's eyes, I consider it a fault. I like to see this petal nearly horizontal except for a curling upward of the end ¼in. or so. The three outer



3.—*A medium-sized primulinus whose petals, although well disposed, show too much of a reflex.*



4.—*The daintiness of the primulinus is here shown to advantage but the stem is too prominent in this specimen.*

Digitized by Google

petals should be wide open like a butterfly's wings, with a dainty, but by no means pronounced reflex backward at their tips. In general outline, the flowers are triangular and, in some varieties, a trifle stiff looking. (The ruffled or crimped petals of some of the newer large-flowering varieties, such as A. B. Kunderd or Purple Glory, would be a decided acquisition in this class and would dispel any suspicion of formality.) Just a slight nodding or drooping of the florets, gives a demure and altogether charming appearance, but a few kinds develop this virtue so far as to become a fault; we like to see the faces of our prims. without having to hold them above our heads. Another defect in just a few prims. is the tubular shape and like their larger brethren, an open flower is to be preferred. As regards size of the blooms, the well known Orange Brilliant is among the smallest, while Orange Queen and Alice Tiplady are representative of the larger prims. Most of the named kinds fall between the two, such as Hermoine, Atalanta, etc. My own preference in respect to size is for a "medium to large" form, somewhat after the type of Salmon Beauty. A number of prims. are thin in the texture of their petals, and there are very few which would not bear improvement in substance. The flower stem should be long and wiry, not with a twist or two in it such as one finds in Orientale and sometimes in Souvenir, and the placement of the florets should be regular as in the large-flowering gladioli. The two sides of florets facing in opposite directions and exposing the whole length of the stem is a defect. I like to "see daylight" right round every floret and any suspicion of crowding or overlapping of florets is certainly a fault much more serious in the primulinus hybrids than in the large-flowering varieties. About three open blooms and one half-opened bud on each spike are sufficient to give a nice colour effect, a smaller number of open flowers making them appear "all stem." My ideal bunch of prims. would compare, for lightness, with a bunch of sweet peas. C. H. A. S

MOWING MACHINES AND THEIR SELECTION

IN THIS SECOND ARTICLE IS DESCRIBED A NUMBER OF SUITABLE SELF-PROPELLED MACHINES, ANY ONE OF WHICH WILL PROVE SERVICEABLE IN THE UPKEEP OF MODERATE-SIZED AND EXTENSIVE LAWNS AND LARGE SPORTS GROUNDS.

THE application of motor power to the mowing and rolling of grasslands is a comparatively recent innovation, but it is undoubtedly an introduction which has come to stay. While it is only a few years ago since the first self-propelled machine made its appearance, such rapid strides have been made in the evolution of the general idea that the up-to-date machines listed in the 1926 catalogues bear only a very faint resemblance to the original types. Most of the earlier machines consisted of an ordinary hand or pony mower with a small petrol motor built on the framework and connected to the driving roller. While this idea was for a time satisfactory, it soon became evident that, in most cases, the original framework and mechanism of the machine would not withstand the constant vibration and jarring which the motor caused in working. Manufacturers have now solved this difficulty, and the motor mower of to-day is practically a self-contained unit, designed, like the chassis of a motor car, by experienced motor engineers and capable of bearing the strain and stress imposed by constant use. For use on large lawns or sports grounds they undoubtedly go a long way towards that saving of expensive labour which is usually so important, while the difference between the initial cost of an up-to-date motor machine and the older type of hand machine can generally be saved by their economical working during the first season. Neither must their general efficiency be lost sight of. The secret of good mowing lies in the size of the cutting cylinder, the number of the knives and the speed at which they revolve. It follows, therefore, that a machine which, by its own power, can cover the ground at a fair pace, thus automatically increasing the revolving speed of the cutting cylinder, has a great advantage over a hand machine, the speed of which is naturally governed by the energy displayed by the operator.

As in the case of hand machines, prospective buyers are confronted with a large and comprehensive number of models from which to select a suitable machine. Each different make embodies special attractive points, but as many of these apply particularly to the type and pattern of the engine used, the discussion of these is perhaps a subject which is more fitted for the columns of an engineering journal. Messrs. Ransomes, Sims and Jefferies offer many fine models which are designed to meet the needs of all users. They range in size from the large 42in. machine, which weighs 21cwt. and is driven by an 11 h.p. engine, to the convenient little 16in. machine which weighs but 2cwt. 6lb. and is driven by a 1½ h.p. engine. Messrs. Alex. Shanks are also in the forefront with a fine list of various-sized machines, ranging from the giant 36in. cut with a weight of 13½ cwts. to the nippy little "Jehu" 20in. and "Wizard" 16in. The latter machine is an ideal type for general use in a comparatively small garden.

Messrs. Thomas Green and Sons is another firm whose name and reputation are well known in connection with this subject, and their 16in., 20in. and 24in. light models are well known. In addition to these they also manufacture heavier types up to 42in. cut, and their 36in. machine fitted with driver's seat and steering gear is a particularly useful machine for dealing with large areas.

A machine of outstanding merit which demands attention is the "Atco," made by Messrs. Pugh of Birmingham in all sizes from 14ins. to 30ins. Many up-to-date improvements are embodied in this machine, and I am impressed with the pattern of land roller adopted. The 14in. machine is, I believe, the smallest self-contained motor machine on the market. One of the most remarkable features of the "Atco" Company is their Service Scheme. By means of this not only can new parts be obtained but they will be personally fitted by this progressive firm's representatives without the inconvenience and delay caused by the removal of the machine.

The famous motor manufacturers Messrs. Dennis Brothers are also responsible for a very fine machine which is made in two sizes, 24in. and 30in. respectively, and both models secured the highest possible award at the Motor Lawn Mower Trials, held in Regent's Park, in May last, by the Royal Horticultural Society. The Dennis mower is designed in accordance with the best principles of motor car practice, and includes the fitting of differential gears to the driving rollers; oil circulation by pump, gear-driven from the engine; separate clutches to roller and cutter cylinders, etc. A trailer seat can be fitted to both models, and the 4 h.p., 4-stroke engine is powerful enough to draw the trailer and driver up steep gradients and to travel on the level up to five miles per hour.

The Auto-Mower Engineering Company are the manufacturers of a machine which can be obtained in sizes from 15in. to 30in. The aim of the manufacturers has been to construct a simple machine without sacrificing efficiency, and it would seem that this has certainly been accomplished. It is manufactured almost entirely of steel and all rotary shafts are mounted on ball bearings, while the height of cutters can be very easily adjusted without the use of tools.

One seldom sees a motor mower of the side wheel type, and the "Pennsylvania Moto" mower is all the more interesting on this account. The side wheels, of course, do away with the land roller, and, considering it has a cutting width of 27ins., its total approximate weight of only 200lb. is a factor which will be considered favourably by many. The manufacturers claim that it will cover from four to five acres per day, with a petrol consumption of about one gallon. For really hard and rough work this machine is to be strongly recommended.

No article on power machines would be complete without some reference to the well known "Mower Pusher" attachment. This consists of a very ingenious separate motor unit which can be connected at will to most makes of ordinary hand mower, lawn sweeper or roller. It is so arranged that the operator just sits on the attachment and guides the machine. It is simple and extremely economical in working. A. J. C.

ALPINE FLOWERS AT WESTMINSTER

THE great floral feature of the meeting was the superb collection of hippeastrums shown by Lieutenant-Colonel Sir George Holford, from his famous garden at Westonbirt, Gloucestershire. It is several years since a really large group of these handsome lilies has been seen, and never before have they been shown so finely. As ever, it was the new colours that attracted most, and of these the very best were the lovely little New Pink Pearl, the gorgeous rose cardinal-coloured Cardinal Beaton, of immense size and perfect form; Cardinal York, deep old rose; Black Knight, crimson maroon; Flashlight, orange; Rose Brocade and Pink Topaz, which have the base of the flowers feathered with white.

The most striking exhibit among the alpines was the rock garden for which the Hon. Vicary Gibbs (gardener, Mr. Beckett) was awarded a gold medal. This was a steep bank of rock traversed by a cliff path and planted, perhaps, a little too lavishly with brilliant plants and flowering shrubs. Torrents of azaleas and drifts of Daphne Cneorum overwhelmed magnificent plants of Haberlea virginalis, Daphne rupestris and Androsace arachnoidea. Very old specimens of Juniperus compressa and Pinus albertiana conica had acquired with age something of the solidity of the rocks with which they harmonised so admirably, and Taxus baccata pygmæa aurea made a rounded hummock of dull yellow.

Messrs. Waterer showed Iris cristata, many vigorously flowering plants of the reputed difficult Viola pedata; Genista sericea, a trailing woody little broom; Anemone palmata alba, a stocky anemone that has strayed into Europe from Africa; and several forms of Anemone nemorosa, of which Alleni, large, solid and deeply coloured, is perhaps the best.

Messrs. Maxwell and Beale brought up some interesting new mossy saxifrages. Picture, white, flushed and veined with pink from a dark centre; Queen of the Belgians, carmine veined crimson (and much prettier than it sounds); Wenlock Peach, shaded pink; and Saxifraga lævis, whose foliage turns red in winter.

Messrs. Hodsons, Limited, showed Ranunculus graminifolius, a clear-cut design of grey, spiky leaves and pure yellow flowers; Dianthus alpinus, and the very dwarf Erigeron leiomeris with large, cool lavender flowers.

Messrs. W. H. Rogers and Son showed some interesting small shrubs. Iberis saxatilis, whose creeping woody stems and almost black leaves suggest some dark conifer until the many heads of chalk white flowers appear; Azalea serpyllifolia, a delicate little bush with very small leaves and dainty lilac pink flowers.

Messrs. Prichard showed off the floriferousness of their Ramondia pyrenaica in a large clump on a miniature cliff, and exhibited a dark form of Cortusa Matthioli (C. pubens), which is rather superior to the type.

One of the best of Mr. F. G. Wood's plants was Potentilla fragiformis, with soft strawberry leaves and very large, saucer-shaped flowers, clear yellow with an orange centre. An old plant, but a rarity, was a hose-in-hose oxlip and a new plant (though now well known and appreciated), Primula secundiflora, which is a wine-coloured version of P. sikkimensis, delicately powdered with white bloom.

Mr. Clarence Elliott made a *pré fleuri* of gentianella and the pale, silky bells of Sisyrinchium filifolium in a dark corner that scarcely did justice to the robust terra-cotta red of The General and the violet of The Professor, two brilliant hybrids of Primula pubescens, or to a large group of the grandiflora variety of Daphne rupestris hiding themselves with fragrant pink flowers.

Messrs. Baker of Wolverhampton showed Primula chrysopa, whose delicate lavender is almost blue, and a bank of Armeria cæspitosa.

Mr. J. Robinson of New Eltham made a pleasant little garden of sedums, aubrietia and the tangerine-scented Thymus azoricus.

Messrs. Tucker and Sons showed the minute Bulgarian pink Dianthus microlepis; Myosotis Rehsteineri, a mat-forming forget-me-not; a soft apricot form of Geum Heldreichii, and many other good plants.

Mr. J. C. Allgrove showed a form of the common primrose with flowers twice as large as the type which was found in a wood in the west of England by Miss Evelyn Arkwright, whose name it bears.

Among interesting plants exhibited by Messrs. Jeans and Trowbridge were Cyathodes ericoides, a powerfully scented, heather-like

AN ATTRACTIVE GREENHOUSE SHRUB, ANOPTERUS GLANDULOSUS.

alpine with waxy white bells from New Zealand that has proved quite hardy; Iris lacustris, an exquisite miniature of I. cristata; the flat, open-flowered Trollius pumilus; and Felicia petiolata, a rambling little shrub with delicate, lavender pink cineraria flowers on tall, slender stems.

Mr. E. M. Preston showed not only that it is possible to grow our native terrestrial orchids, but that the fly, the sweet-scented, the butterfly and the spotted orchids are well worth the trouble.

Cinerarias and their near relatives, the senecios, were shown as very decorative pot plants. Messrs. Sutton and Sons had a good group of their new variety (see New and Rare Plants); while Mr. E. M. Preston of The Warren, Hayes, sent a well grown batch of Senecio Beauty of Cambridge, well furnished with the white purple blush tipped cineraria-like flowers.

The scented Cape pelargoniums from Wisley attracted a deal of attention, partly on account of the pungent, refreshing scent of the leaves, but also by reason of the decorative value of the flowers of some of the species. In the Annexe Messrs. Jarman and Co. had a good collection of trusses of bloom of the zonal pelargoniums which made a very bright display. They had a good selection of both the double and the single flowered varieties.

The possibilities of a good strain of schizanthus when sensibly grown was illustrated by Messrs. Dobbie and Co. in their splendid collection of Dr. Badger's strain, which has such a delightful range of colouring. The seed was sown early last September, and the plants have been grown under cool conditions ever since.

Mimosas, as pot plants, were also displayed in great excellence. Messrs. Stuart Low and Co. had very floriferous bushes of Acacia pendula, A. armata and A. junipifera. Other beautiful plants in their collection included the yellow Richardia Elliotiana, hippeastrums, gloxinias and the sweetly scented Boronia megastigma.

Flowering trees and shrubs made a bright display. Mr. R. C. Notcutt had a beautiful group of the best pyruses, Japanese cherries, berberis and lilacs. Messrs. R. W. Wallace and Co. showed floriferous bushes of rhododendrons, including the Earl of Athlone, Daphne Millais and Douglas McEwan, and they also had good examples of Japanese azaleas; while Messrs. L. R. Russell and Co. again exhibited clematis in flower. Flowering crabs were also displayed by Messrs. J. Cheal and Sons, with the orange-coloured Cydonia Maulei and the dwarf Berberis Crawley Gem. Mr. G. Reuthe had many trusses of various rhododendrons.

The earliness of the season was illustrated in an exhibit by Mr. J. C. Allgrove, who lifted a large clump of the lovely Pæonia obovata alba from the open ground; this received a first-class certificate at the Chelsea Show last year. The tall spikes of Rheum palmatum rubra in his group were very decorative.

Carnations were shown in abundance by the usual exhibitors, and there were small collections of roses. Mr. G. H. Dalrymple had another large collection of the Bartley strain of Primula pulverulenta, and included a few plants of P. Littoniana, Miss Christy's New Polyanthus, Greenway's Glory, was very charming. Polyanthuses were also shown by Messrs. John and A. Crook and by Mr. G. W. Miller.

Although the Daffodil Show is a thing of the past, Messrs. Barr and Sons were able to set up many excellent seedlings of various types and a large quantity of named sorts. Of the latter, Suda, which has a long, fluted primrose trumpet; Rosary, with an old ivory trumpet; and Hexagon, an immense Incomparabilis with a long, pale yellow tube, were the very best.

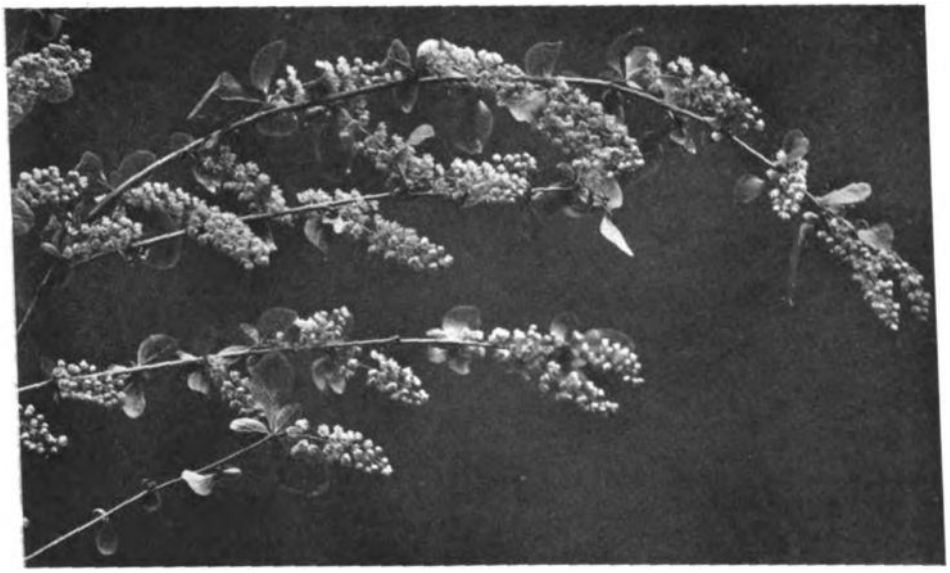
In the Gallery, Messrs. R. H. Bath, Limited, had narcissi and tulips; and Messrs. F. H. Chapman, Limited, showed a few good seedlings of the Barrii and Poeticus types with some named varieties.

A most attractive garden of Darwin tulips was laid out by Messrs. Carter and Co., who had generous quantities of Centenaire, pink; Roi d'Islande, rich pink; Velvet King, shining purple maroon; Valentine, satiny heliotrope; and Mr. Farncombe Sanders.

Messrs. Charlesworth and Co., Haywards Heath, staged the only group to which a silver Banksian medal was awarded. It contained a very dark variety of Lælio-Cattleya St. George, some fine examples of Miltonia William Pitt, with crimson flushed segments, and a distinct variety of Odontioda Madeline, with dark yellow flowers having reddish blotching. An interesting plant was staged in Wilsonara Wendy, with elongated spikes bearing large reddish flowers; and species were represented by the pretty Cypripedium niveum, with flowers of porcelain white, and the handsome Dendrobium thyrsiflorum.

In conjunction with this Show, the National Auricula and Primula Society held their floral meeting for 1926. Although the number of exhibitors was somewhat small, there were several good groups of the quaint old-fashioned Dusty Miller. Mr. James Douglas won first prizes in various classes, both for alpine and show auriculas. The

Digitized by Google



THE GRACEFUL FLOWERING SPRAYS OF BERBERIS KANSUENSIS.

alpine varieties Day Dream, Morning Star and Argus, shown by Mr. Douglas, were excellent specimens. Mr. E. Heron Allen staged a number of well grown plants; Mr. C. Kirch exhibited, among others, an attractive white-edged seedling; and Mr. A. S. Hampton won a first prize for his single white-centred alpine auricula.

Inyetsee, a sulphur yellow variety shown by Mr. J. Douglas, was considered the premier fancy auricula; and Argus, a dark plum with a white centre alpine auricula, also shown by the same grower, was awarded the prize for the premier alpine auricula. The "James Douglas Memorial Challenge Cup" was awarded to Mr. A. S. Hampton for six beautiful blooms of alpine auriculas. Polyanthuses and primroses were exhibited by Mr. G. A. Miller, his prize varieties being Dawn, large clear blue primrose; Sunset, a deep shaded orange polyanthus; and Mme. Pompadour, a purplish-crimson primrose. Mr. Heron-Allen received a first-class certificate for an excellent grey-edged unnamed variety.

NEW AND RARE PLANTS.

AWARDS OF MERIT.

ANOPTERUS GLANDULOSUS.—This very attractive greenhouse shrub, which was introduced from Tasmania in 1823, does not seem to have ever been much cultivated. It branches freely and bears large shining leaves, much the shape of those of the Portugal laurel, though rather larger, shining, and having shallow serrations. The fairly large, round, white flowers are borne in erect terminal racemes. Shown by Lieutenant-Colonel Messel, O.B.E., Nymans, Handcross.

BERBERIS KANSUENSIS.—This is a most distinctive berberis. It was originally discovered by a Russian in western China many years ago. It is deciduous and extraordinarily vigorous, many shoots exceeding 3ft. in length every year. The leaves are up to 4ins. long and 3ins. wide, while the flowers are a bright yellow and hang in numerous short racemes. It is ascendent in growth and obviously becomes a very large shrub. Shown by Mr. E. H. M. Cox, Glendoick, Perthshire.

BOMAREA BANKSII.—These handsome South American twining liliaceous plants are rarely seen outside botanic gardens, though they have much to recommend them as climbers for the cool greenhouse and are of easy culture. The flowers are of deep orange colour on the outsides, while the tube is yellow within and freely spotted with crimson. Shown by the Cambridge Botanic Gardens.

BRACHYSEMA LATIFOLIA.—A strikingly handsome shrub, suitable for growing as a pillar plant in the cool greenhouse. The slender, graceful stems and the under sides of the small leaves are densely covered with silky hairs. The brilliant, scarlet crimson, pea-shaped flowers are borne in short clusters in the axils of the leaves. Shown by Lieutenant-Colonel Messel.

CINERARIA INTERMEDIATE PINK.—This is a highly decorative greenhouse pot plant. It is of compact yet spreading habit and bears large quantities of good sized flowers of a lovely soft pink shade. Shown by Messrs. Sutton and Sons.

CISTUS WINTONENSIS.—This is a pretty little gum cistus, furnished with grey foliage and stems and bearing relatively large, flattish round, milk white flowers which have a distinct purplish maroon zone. It appears to be a low, semi-rambling shrub suitable for the rock garden. Shown by Hillier and Sons.

HIPPEASTRUM MAGIC.—A handsome flower of large size and rich deep scarlet colour. A white band runs from the middle of each floral segment to its base. This and the two following were shown by Lieutenant-Colonel Sir George Holford, C.V.O., Westonbirt, Tetbury.

H. NEW PINK PEARL.—A very delightful flower, rather smaller than most, but of perfect rounded form and lovely pink colour.

H. THE BRIDE.—A splendid white variety of large size and with a little green in the centre of the flower.

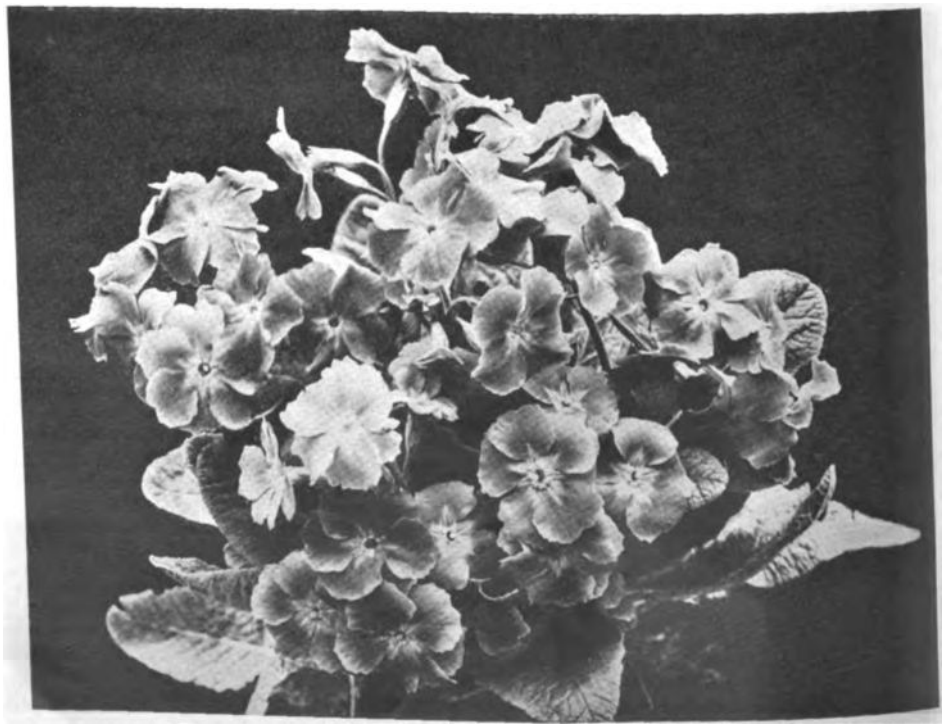
POLYANTHUS GREENWAY'S GLORY.—The flowers are large, freely produced, and of an uncommon and very attractive velvety Venetian red colour, with a yellow eye. Shown by Miss Charlotte Christy, Boyton Cross, Chelmsford.

RHODODENDRON DAME NELLIE MELBA.—A very handsome truss of perfect form and of large, round, widely opened flowers of beautiful pink shades which have two narrow rows of carmine and chocolate spots on the lower segments. The pink colour is deeper on the outsides of the flower. Shown by Mr. Lionel de Rothschild, Exbury, Hants.

RHODODENDRON LORD SWAYTHLING.—This is a beautiful hardy hybrid which flowers when the bush is quite dwarf. The large flowers are of delicate pink shades of colour which pale towards the margins and are much deeper on the outsides of the flowers. Shown by Messrs. R. W. Wallace and Co.

ORCHIDS.

CŒLOGYNE LAWRENCEANA VAR. SUPERBA.—This handsome species bears the name of Sir Trevor Lawrence, by whom it was exhibited at the meeting of the R.H.S. on March 28th, 1905, when it obtained an award of merit. This plant was introduced from Annam by Messrs. Sanders, and the same firm have now shown a much superior type, with larger flowers and with the well known characters of the labellum considerably developed. It belongs to the speciosa group, but is taller in habit, in which respect it approaches C. Micholitziana. The sepals and petals are light buff yellow, and the front lobe of the labellum cream white with a deep orange disc. The labellum bears several prominent fimbriate keels, which are brownish, as also are the side lobes. Shown by Messrs. Sanders, St. Albans. First-class certificate.



A VENETIAN RED POLYANTHUS, GREENWAY'S GLORY.

SALAD VEGETABLES IN THE GARDEN

SALAD vegetables figure largely in the imports during the course of the year, and yet there is no reason why home growers should not get more of this trade. Though, perhaps, saladings are more easily raised in early summer than in winter, spring or autumn, there is nothing particularly complicated in this business of growing salads for use all the year round. It is mainly a matter of scheming, knowing what to sow and when to sow them, and keeping up to date with those sowings.

The principal saladings are beet, chicory, corn salad, cucumbers, endive, lettuce, mustard and cress, small onions, radishes and tomatoes. All these are easily cultivated, and if a little care and common sense be exercised in putting them upon the market at the proper time, profit can be made at home that at present goes into the pockets of foreign growers.

Beetroot may be had all the year round, for roots can be stored and will usually keep well till spring-sown globe beet come into use. If young beet are required, the globe kind can be sown in a frame, the seedlings being thinned out to a few inches apart, then thinned again, and the final thinnings made use of for salad.

The value of chicory does not lie in the summer months, when cucumbers, tomatoes, radishes, etc., are abundant, but during winter, when it provides a change in the list. The process of forcing is such a simple one as to bring it within the reach of everyone who has a cellar or a shed that is properly dark, and where the temperature is reasonably equable. There are two varieties of chicory cultivated in this country, of which the witloef is the easiest to grow, and produces leaves of excellent flavour.

Corn salad, or lamb's lettuce, is mostly in request in spring, when properly dressed salads are always appreciated. Seeds can be sown at practically any period of the year, but those put in in August and September generally give the best returns.

For a very early supply of cucumbers the seed must be sown in December, and the plants grown in the greenhouse. Another sowing should be made in February and again in April, these plants being grown in a frame. In April and May the outdoor ridge varieties may also be sown — under glass — for planting outside.

Endive is mostly grown for autumn and winter use, for it stands the cold weather so much better than lettuces. Sow in August, lift the plants when ready and set them fairly close together in boxes or in a frame or on the floor of a glasshouse. The best way to blanch them is by covering to ensure darkness. Good varieties of endive are green curled and winter curled.

The first sowings of mustard and cress should be made in March in boxes about 12ins. square and 2ins. deep. The soil in the boxes must be well pressed down and the seed sown regularly over the surface. When placed in a greenhouse or frame the seed will germinate in from six to eight days, and a further supply may be sown in another box for succession. Mustard and cress can be grown all the year round if there is a little artificial heat. Two sowings of mustard should be made to one of cress, that is to say, mustard should be sown once a fortnight and cress once a month to procure a succession.

Young spring onions, as they are called, are really sown in summer or autumn, ranging from the end of July to the end of October. The Tripoli and Giant Rocca are the kinds that produce the best plants for salads.

Radishes find a readier sale in early spring and summer than at any other season. The reason why they are then sought and appreciated is to be found in the fact that samples are then more uniformly young, tender and of good quality, though there is no valid reason why the season should not be extended on the basis of successional sowings. Long radishes are generally best for deep ground and for early work, though the variety known as French Breakfast succeeds well on shallow land. For late and autumn supplies red and white turnip-rooted varieties are best, and it is desirable when grown for market to grow a preponderance of white-bulbed, which look showier and better in the bulk than an equal or greater number of red. The radish, more than any other vegetable, is ruined by slow growth. Rapid growth should therefore be aimed at, and roots of medium size are the most marketable.

Both cos and cabbage varieties of lettuce should be grown, and to keep up a supply during the summer and autumn months it is necessary to sow seed at intervals of from ten to fourteen days. For early lettuce, sowings may be made in early spring in gentle heat in frames, which will be ready to plant out at the end of April or the beginning of May. Later on, when summer sowings are made, the young plants should not be moved, as transplanting often causes them to bolt or run to seed.

Tomatoes may be cultivated successfully either in or out of doors, and though the plants are fairly productive, the limited culture cannot be induced to give very large returns. Unlike the cucumber, for instance, the tomato plant does not give successional supplies, but forms and ripens its full crop, and the work is then finished. The best tomato to cultivate is of the smooth kind, weighing, on an average, eight to the pound, as these are most in demand.

CORRESPONDENCE

NAMES OF EARLY POTATOES.

SIR,—The note which appeared in THE GARDEN of April 10th, page 227, on the confusion of the names of early potatoes by Mr. Geo. Stuart, Edinburgh, should prove to be a rather interesting subject to those who grow a few lines of "earlies" as well as to the commercial grower. To the enthusiastic potato grower it must be a somewhat depressing revelation for him to know that he may have been buying and planting the Duke of York potato under the impression that it was Midlothian Early, Victory, etc., or some other of the numerous Duke family that he fancied best. To be told that Duke of York, Victory and Midlothian Early are simply one potato masquerading under three or four different names appears to be what the Board of Agriculture has found to be the case.

To those who pinned their faith on some one of these potatoes the information will not be cheering, and is a rude reflection on their perception of characteristic points which distinguish the varieties.

It sounds like a feat of jugglery when we are told that from a pit in springtime some nurserymen and potato merchants can produce three or four varieties of potatoes with distinct names, which in autumn only contained Duke of York. If this be correct, as we assume it to be, from what Mr. Geo. Stuart says, this means of supplying the various needs of customers must prove of great convenience to trade growers. That there was a distinct difference in the characteristic points of the potatoes originating from the Duke of York variety when first coming into commerce there is no reason to doubt. Despite all the scientific findings and research work of the Board of Agriculture on the matter, one has to believe the evidence of one's own eyes and results obtained by experience of the potatoes in question. The reversion or deterioration back to the present type, which now exists among them, is without doubt greatly due to a slipshod and careless selection of seeds and also to unscrupulous growers supplying seeds of Duke of York when stocks of Victory, Midlothian Early, etc., ran short. It is owing to these reasons, in my opinion, we are now faced with such a hopeless mixing of these potatoes and, of course, not a confusion of names at all as Mr. Stuart says.

I have grown Victory ever since it came into commerce, in frames, early borders and in the open ground alongside Duke of York. The results from these experiments, I am bound to say, has been entirely in favour of Victory, the true Victory being whiter in the flesh, giving a far heavier yield of tubers and being much more appreciated on the table. These results have justified me in discarding Duke of York. The potato Victory was obtained by the late Mr. Sim of Fyvie, Aberdeenshire, from a cross between Duke of York and Fyvie Flower. This infusion of new blood resulted in a potato of superior cropping qualities and other good points which I have mentioned. True seeds of this potato are no doubt difficult to obtain now (as well as the others of Duke type), but Messrs. W. Smith and Sons, seedsmen, Aberdeen, from whom I first obtained it, and who brought it into commerce, always kept a pit which could be relied upon, and contained Victory only.—WM. GRANT, *Kincardineshire*.

RHODODENDRONS IN VARIOUS AREAS

SIR,—In your issue of March 27th, page 195, under the above heading, I was rather astonished to find no report from Argyll, where there are several very fine collections of rhododendrons. Being a "west coast amateur," quoting from Sir Herbert Maxwell's letter, page 238, I took pencil and paper to a neighbouring garden, and thought it might be of interest to your readers if I named some of the rhododendrons I found there.

Digitized by Google

Those then in flower were RR. Augustinii, polylepis, Keysii, Shilsoni, arboreum × Shilsoni, barbatum, campanulatum, quinquefolium (alba), Falconeri, irroratum, Davidsonianum, Roylei, Kæmpferi, pachytricum, impeditum and Wilson's 1330, 1205 and 1275. There were several others with no name plates. Among the general collection were RR. racemosum, longesquamatum, triflorum, sino-grande with leaves 22½in.-long, Watsoni, dahuricum, calophytum. Thomsoni, ambiguum, Aucklandii, micranthum, habotrichum, niveum, Fargesii, oleifolium, rhombicum, rubiginosum, xanthinum, Hodgsonii, Pieris Forrest 8945, sutchuenense, moupinense, maculiferum, Metternichii, decorum, neriiflorum, orbiculare, fulvum, torlonianum, chartophyllum, calophyllum, callimorphum, brachycarpum, benthamianum, auriculatum, zelanicum, oreodoxa, Dalhousiæ, dichroanthum, Kingdon Ward 3952, Farrer's 17610 and 16806, Schlippenbachii, pseudochrysanthum, Maddeni, Williamsianum, galactinum, argyrophyllum, intricatum, russatum and also many others with no names. I do not think any "west coast amateur" need have any hesitation in trying any of these, given suitable surroundings, as the foregoing have all withstood 18° of frost this winter, which is exceptionally severe for us here.—M. CAMPBELL, *Ardfern*.

THE STAKING OF PLANTS.

SIR,—I was much interested in a letter on the above subject in your issue of April 10th, page 226. I am of the opinion that the method of staking therein mentioned is not often adopted when such plants as asters and delphiniums are being dealt with, though the fact that it effectively resisted wind is proved by your correspondent's experience.

Undoubtedly much trouble with staking arises from the fact that in many cases sufficient attention is not given to making the stakes firm. When dealing with 5ft. high asters and delphiniums I consider that the "pushing in" of the stakes is not enough, they must be driven in with a mallet if they are to stand the strain of a season. Good sound hazel stakes, if driven in at an angle which leaves the tops of the stakes slightly farther apart than the bottoms, will stand a vast amount of wind and if they are placed in position before the plants have been damaged by wind then "waist-bands" can be applied as the growths lengthen and both stakes and strings will be hidden by leaves before the flowers appear.

If I am not encroaching too much on your valuable space, I should, while on this interesting topic, like to mention a method of staking which is being adopted in a neighbouring garden. Delphiniums are being dealt with and the plants are now about 18ins. high. Round each plant three stakes are placed as if the ordinary plan of staking was being followed. Each of these is driven into the ground firmly so that roughly 2½ft. of the stake remains above the surface. The three stakes in position, a piece of 2in. mesh wire netting, previously cut to agree with the circumference of the plant, is slid over the stakes and suspended at a distance of a few inches above the top of the plant by tying the wire netting at each of the three stakes.

A piece of string is passed round the stakes about a foot from the ground to ensure that all growths proceed upwards through the netting and I presume that when they are through another piece of string will be wound round the top of the stakes.

On the face of it certain advantages and also disadvantages are very apparent, but as an onlooker I feel inclined neither to commend nor condemn the method, but pass on the information as a matter of interest.—W. HOWELL, *Watford*.

THE SPRING ROSE SHOW

THE National Rose Society held its first rose show of the year at the Royal Horticultural Society's Hall on Friday last and the high quality and general all-round standard of excellence which has come to be looked for at this show was fully maintained on this occasion. The amateur exhibits were distinctly above the average, both in quality and quantity, while the nurserymen's exhibit, although good, had suffered to some extent by the recent adverse weather conditions. The attendance was large and the majority of visitors found much both to interest and instruct them in the new roses, many of which were on show for the first time, and which illustrated the constant changes which are being wrought in our national flower.

In the nurserymen's section for groups of roses, Messrs. Chaplin Bros. and Messrs. Easlea both exhibited and gained respectively first and second prizes. In the circular group of Messrs. Chaplin some fine varieties were shown, of which the brilliantly coloured Royal Scarlet was the most outstanding as a central feature. Other varieties, such as the decorative Paul's Scarlet Climber, American Pillar, Sander's White and Lady Godiva were shown with a surround of hybrid teas and hybrid pernetianas, including Ophelia, and Mme. Butterfly, all in good shape and condition.

The central feature of Messrs. Easlea's exhibit was formed by a varied group of their fine new hybrid Wichuraiana Thelma, which, although not a perpetual, has very persistent blossoms. Surrounding this were to be found many hybrid teas and pernetianas, including fine blooms of Mme. Abel Chatenay, Ophelia, Hoosier Beauty and Molly Sharman Crawford.

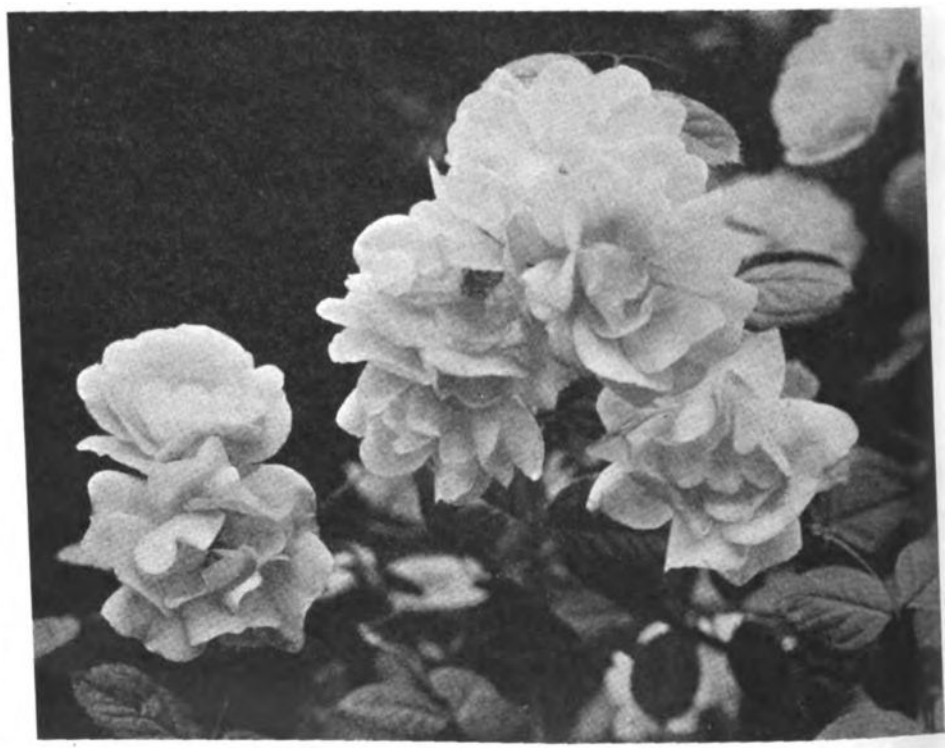
In class two, for a group of cut roses, the first prize went to Mr. Elisha Hicks, for a very attractive group. The background was composed of many climbing polyanthas, including Dorothy Dix, Coral Cluster, Austrian Yellow and Paul's Scarlet Climber, which made a brave show. Some excellent blooms of Clovelly, Mrs. Elisha Hicks, Maréchal Niel, Climbing Lady Hillingdon and Charles E. Shea, were to be seen in front of the stand.

The second and third prizes in this class were awarded to Mr. George Prince and Messrs. B. R. Cant respectively, both with well arranged collections. On the former stand the chief varieties which we noted were K. of K., Betty Uprichard and the snow white Pax, while on Messrs. Cant's a basket of the sulphur yellow Mrs. Beatty was most attractive.

The class for six pillar roses in pots was poorly represented, only one exhibit from Messrs. Chaplin Bros., which gained first prize, being on show. The varieties shown were the pink and white Dorothy Perkins, The Beacon (crimson), Blush Rambler, Coronation and Chatillon Rambler. The plants were all well grown and were from 6ft. to 7ft in height.

Groups of polyantha roses in pots were shown by the Rev. J. H. Pemberton and Messrs. Cutbush, who gained first and second prize respectively. The exhibit of the former included Edith Cavell, White Orleans, the crimson Eblouissant, Ellen Poulsen and the delicate pink Echo grouped to form a carpet, relieved by standards of Ella Poulsen and Lady Reading. Messrs. Cutbush's well arranged little group contained some striking varieties, of which the tiny buttonhole blossoms of Orange King were delightful. Although glowingly described as Orange King, the colour is more of a flesh salmon. It is a most attractive sort if it remains true to type. Chatillon Rose was another dwarf perpetual polyantha shown. It has flowers of a rose pink fading to white in the centre with a central cluster of yellow, and is very floriferous.

Classes five and six for cut blooms in exhibition roses were both well represented.



THELMA, A FINE WICHURAIANA RAMBLER, INTRODUCED BY MESSRS. EASLEA, AND WHICH RECEIVED A CERTIFICATE OF MERIT.

Digitized by Google

The first prize in the former class went to Messrs. B. R. Cant, who staged twenty-four excellent blooms, among which Sovereign, Mme. Butterfly, Covent Garden and Phœbe were prominent. Mr. Elisha Hicks gained the second prize with many choice flowers.

There were three entries in Class Six and Mr. A. T. Goodwin was easily first with his twelve large sized blooms of Maréchal Niel. He also gained with this exhibit the silver-gilt medal for the best rose in the Show shown by a nurserymen. The second and third prizes went to Messrs. B. R. Cant and Mr. Elisha Hicks respectively, who staged Rev. F. Page Roberts and Clovelly.

Although only a few nurserymen showed roses in baskets, the majority of specimens seen were of an excellent standard. The first and second prize baskets of blooms shown by Mr. A. T. Goodwin of Maidstone and Messrs. Alex. Dickson and Sons of Newtownards, respectively, were, indeed, fine. Mr. Goodwin had a basket of very large blooms of Maréchal Niel, and Messrs. Dickson's well arranged basket of the beautiful and fragrant Fred T. Harrison was admired by all. The latter variety is a deep crimson with long, pointed buds. The gold medal seedling rose of deep shaded orange, named Lady Margaret Stewart, was awarded a first prize. The foliage of this new variety is an attractive dark green and quite glossy. In another class for two baskets of cut blooms of two distinct varieties, Mr. A. T. Goodwin selected spotless blooms of Climbing Frau Karl Druschki and a number of well grown Marechal Niel. These gained a first prize, while Mr. Elisha Hicks' baskets of Mme. Butterfly and Mrs. Herbert Stevens received the second prize.

The table decorations arranged by the trade growers were first class. Mr. L. R. May's table was considered by the judges to be the best. A large central bowl and small vases of Mme. Butterfly and asparagus fern adorned the table. The second prize table was that of Mr. C. Tisdall, who, with the variety Roselandia, made a most attractive group. The prize bowl of Mme. Butterfly shown by Mrs. L. R. May was in perfect condition and Mr. C. A. Tisdall's exhibit in the same class was remarkably good.

The class for six new roses, put into commerce since the beginning of 1922, was disappointing, only Mr. Elisha J. Hicks exhibited and he was awarded the first prize for very moderate blooms. The three best were John Hart, deep pink; Lady Verey, soft pink; and Muriel Wilson, pale lemon.

Groups of roses arranged on a space measuring 5ft. by 3ft. were excellent. Mr. E. J. Holland, Epsom, was deservedly first, and he set up quite a delightfully arranged group of first-class blooms. Unfortunately for the visitors, these splendid blooms were not named, but the principal varieties were Mrs. Foley Hobbs, Louise Crette, Golden Emblem, Gorgeous and Coronation, while in front he had a charming vase of the rich crimson, single flowered Rosa Moyesii. Mr. H. R. Darlington, Potter's Bar, was second in this interesting class.

Mr. Holland was also triumphant in the class for twelve blooms, in not fewer than six varieties, where he had magnificent blooms of Wm. Shean, Mrs. C. Lamplough, Earl Haig, Mrs. Foley Hobbs, Gorgeous and Dean Hole. Mr. Sydney F. Jackson, Epsom was second with an exhibit of much merit. Mr. Jackson included Augustus Hartmann, Mrs. C. Lamplough and Wm. Shean, of a high standard.

The quality was not so high in the class for six blooms and the two best exhibits were placed equal firsts. Mr. John N. Hart, Potter's Bar, showed Wm. Shean, Mabel Morse and Mrs. Foley Hobbs in his exhibit, while Mr. C. H. Rigg, St. Albans, had Bessie Chaplin, Mrs. F. Dennison and Wm. Shean among his best blooms.

Two exhibits of six blooms of one variety were superb and both were of Mrs. Foley Hobbs. Mr. J. N. Hart had half a dozen in exceedingly fresh and even condition and Mr. E. J. Holland, the second-prize winner, had the consolation of winning the silver-gilt medal offered for the best bloom in the amateurs' section, with a magnificent specimen in his exhibit.

The blooms in the class open only to growers of fewer than thirty pot plants were of good quality. The best were shown by Mr. C. Chalmers, Harrow, who included Mrs. Foley Hobbs, Courtney Page, Mrs. R. D. McClure and Wm. Shean. Mr. Harold Mitchell was a good second.

Although Mr. Sydney F. Jackson was the only exhibitor of six vases of roses, any varieties, his exhibit was fully deserving of the first prize which was awarded. He showed vases of mixed varieties of great merit, and the chief were Gorgeous and J. G. Glassford.

The baskets of roses were very attractive. The best of one variety was that of lovely blooms of Mrs. Foley Hobbs, arranged by Mr. E. J. Holland, while Mr J. N. Hart was second with a very good exhibit. The basket of mixed varieties which won a first prize for Mr. H. Oppenheimer, Caterham, was very delightful and Mr. E. J. Holland was a close second.

NEW ROSES.

There were several varieties which had previously received a certificate of merit and on this occasion two were given a gold medal.

DAME EDITH HELEN.—This gorgeous hybrid tea rose received a certificate last year and on the present occasion it was shown in even greater beauty. It is a fully double flower, beautiful and shapely in all stages of growth and of first exhibition size. The flowers are composed of broad, substantial petals, rich pink in colour and recurve attractively. Added to these merits it has, even when forced, most delightful fragrance and the foliage is very good. It is recommended for the garden and for exhibition. Gold medal. Shown by Messrs. Alex. Dickson and Sons.

LADY MARGARET STEWART.—This beautiful hybrid tea rose also received a certificate last year. It is a very large flower and like the foregoing possesses size without any suspicion of coarseness. The blooms are very dull and made up of very broad petals. The general colouring is pale peach and old gold with a deeper flushing of rich pink on the outsides. It is deliciously scented and the shining, dark green leaves are definitely toothed. Gold medal. Shown by Messrs. Alex. Dickson and Sons.

MAUD E. GLADSTONE.—A fascinating polyantha variety which appears to be very free flowering. It may be described as a loosely formed, old-fashioned rose of mid-pink colouring becoming blush pink at the margins of the petals which are prettily waved. Certificate of merit. Shown by Messrs. Bees, Limited.

THELMA.—This variety was also entered for the Cory Cup which will be awarded at the end of the season. It is a rambler and, as shown, in a large pot, is vigorous and fairly free-flowering. The pollen parent is stated to have been Paul's Scarlet Climber, but the flowers are not so large or so double as in that variety. They are of blush pink colour, which is said to be a reddish-pink during the summer. Certificate of merit. Shown by Messrs. Walter Easlea and Sons.

Other new seedling roses included Ivy May, a pretty hybrid tea variety, shown by Messrs. G. Beckwith and Son, which received a certificate last year. It is a good double of medium size, with recurved petals and has long pointed buds. Saltaire, shown by Messrs. Alex. Dickson and Sons, also received a certificate last year. It is a fully double hybrid tea variety of deep crimson, velvety maroon colouring. Lady Sylvia, shown by Mr. George Prince, also did not receive further award. It is a decorative pale rose coloured hybrid tea variety with long spineless flower stems. Margaret Spaull, a very large, round, hybrid tea variety, shown by Messrs. B. R. Cant and Sons, is sweetly scented and of a yellow shade, with faint blush veining. Joan Cant, by the same raisers, is another very large fragrant hybrid tea rose. The colouring is similar to that of Souvenir de la Malmaison. Everest, a large hybrid tea variety, shown by Messrs. Walter Easlea and Sons, carries the foliage too close to the blooms to be really attractive. The paper white colour is shaded with lemon yellow.

EDITOR'S TABLE.

AT the end of March Messrs. Laxton Bros. of Bedford sent us a few specimens of their new Apple Laxton's Supurb. The apples were in surprisingly good condition, and were firm, juicy and of good flavour. This variety has been raised by crossing Wyken Pippin and Cox's Orange Pippin. It is large, with a yellow skin flushed with red, and the flesh is white, crisp and has a delicious flavour.

SOME PRACTICAL AIDS TO GARDEN EFFICIENCY

IT is about this time of the year that new and up-to-date catalogues are issued, and the little time spent in the sending for, and perusal of, these booklets is usually well worth while, inasmuch as it keeps one *au fait* with all the latest improvements and new inventions which are taking place. Great advances are constantly being made in the design and construction of tools and devices, all tending to reduce the exertion and expense of successful cultivation. The merits of various appliances are often discussed in these columns, and it would, perhaps, be more serviceable if the space at my disposal was first devoted to some of the newer things which are being offered this season. One of the most useful labour-saving devices for use in practically any kitchen garden is either a single or double wheel cultivator. By the use of detachable and interchangeable tools these machines can be used in turn for ploughing, hoeing, etc.; while for stirring the soil between rows of plants they are invaluable. There are several different types on the market, each of which has its particular points. Outstanding makes are the various "Planet Juniors," "Eden Cultivators" and "Retro Cultivators." Often one is approached for information or assistance in the matter of removing or uprooting old trees and stumps. The Australian Monkey Jack is especially designed for this purpose, and is an implement of great power and durability. It is easy in operation, quick in action,

Digitized by Google

and its construction is simplicity itself. It is made in two sizes which will lift up to six or ten tons respectively. Many will be interested to learn that they can procure, at trifling cost, an earth augur which will successfully bore holes of from 6ins. to 16ins. in diameter in any soil. This is an extremely useful tool for setting fence posts or planting small trees and shrubs. It works quickly and easily, and the blades are so arranged that they will clear themselves of the extracted soil as they bore into the ground. An ingenious contrivance, known as the Handy 2 in 1 Ladder, calls for a little attention on account of the many uses to which it can be put to in the average establishment. It consists of a ladder made in two sections joined in the centre with an automatic locking device, by means of which it can be immediately transformed from a long ladder to a step-ladder which will stand independently on its own feet. It is made in various sizes, is light in weight, and can be easily carried and stored. In its extended form it is useful for nailing wall trees, fruit picking, etc., while in its folded position it is invaluable for use in the greenhouse, conservatory or vinery. Spraying requirements are well catered for in the many excellent types of machines which are offered. The good qualities of the various machines bearing "The Four Oaks," "Martsmith" or "Vermorel Eclair" trade marks have been enumerated in this journal on previous occasions, and their general excellence is now so well known as to render further comment unnecessary.

Particulars have just reached me of a small hand sprayer, which was in use at the last Chelsea Show and which struck me at the time as being a very efficient little machine. Known as the "Con-O-Mist," it is extremely simple to operate and requires no pumping while in use. The force of the spray can be regulated by a stop-cock, and it is thus suitable for use on plants of a most delicate nature. It is made in various sizes from 3½ pints in capacity upwards. The "Eclipse Sprayer" is another type which does not require pumping when in use. It is fitted with a hose connection and a valve with strainer combined. The valve is placed into a bucket containing the spray fluid, and the plunge rod is worked in and out until spraying commences; after this no further

THE "LITTLE WONDER" HEDGE CLIPPER.

pumping is necessary, and the operator thus has both hands free to direct the spray. By varying the length of hose and making use of lance extensions, overhead spraying can be carried out from the ground with a minimum of labour.

A very useful appliance for the prevention of the dampness and discomfort caused by kneeling about on wet earth or grass is the "Kneel-on-Air" Mat. This is very neatly made to fit the knees, and is so shaped that it, practically speaking, forms a pocket or cushion of air under each knee when in use—hence its name. It is strongly made of rubber, is waterproof and washable, and is equally serviceable in either house or garden. It is also remarkably cheap.

The desire to be always in front of our neighbour is very prevalent in most of us, and the Chase Continuous Cloche Company has anticipated this by preparing portable cloche protectors for use in raising early flowers and vegetables out of doors. These cloches, which consist of glass sheets fitted into wire frames, are made in all conceivable shapes and sizes. By their use long rows of plants can be quickly brought to maturity without the slightest trouble from wind, rain or frost, and without recourse to artificial heat. In the fruit garden we shall soon begin to notice the havoc wrought by birds and wasps, but here, again, the sundriesman has anticipated trouble and a Major Walker has devised several types of tree protectors which are calculated to foil these pests. They consist principally of portable framework, of various sizes and shapes, which, when covered with fine netting, will isolate the whole tree from outside interference. For low-growing crops the netting supports and brackets made by the House and Garden Sundries Company are also extremely useful for this purpose; while the same firm is also responsible for the marketing of an ideal straining wire for rapidly securing raspberry canes, loganberries and other trees of a similar habit. The need for a practical boot scraper to be placed near the entrance to domestic apartments in order to prevent garden refuse being carried all over the house has also been dealt with. Messrs. "Spade Scrapers" have supplied a long-felt want in placing on the market both their boot scraper and their boot brush. Fashioned with a handle similar to that of a spade, these accessories remove all mud from just those parts of the boot which the ordinary scraper does not touch.

The "Little Wonder" Hedge Clipper is a machine of very recent introduction, but which will shortly become very popular in this country. By its use the trimming of hedges, etc., will become very different from the slow laborious task which it has been hitherto. The manufacturers claim that 300ft. of ordinary sized hedge can be easily clipped by one person in an hour; this includes the top and two side cuts. With very little experience a perfectly even surface is assured. The machine has been tried at the R.H.S. Gardens, Wisley, and has been granted an award of merit.

Many other useful items could be mentioned, but space will not permit, and readers would be well advised to write to such firms as Messrs. William Wood and Sons, Smith and Ellis, Thomas Gunn Limited, Richard Melhuish, Messrs. Holtshapffel and Co., etc., for their new lists if they are desirous of keeping in touch with the latest horticultural improvements.

HEDGE CLIPPING made easy with the "LITTLE WONDER"

A PRACTICAL machine that will clip any variety and shape of hedge five to ten times as fast as the hand shears. It will do better work and make finer hedges with much less effort. Ten feet high hedges may be clipped right from the ground. Easily adjusted for top cutting.

Strong, durable, efficient—a perfectly made and finished labour-saving machine that saves you money every time it trims a hedge.

The "LITTLE WONDER" Hedge Clipper was tried at the Royal Horticuttural Society's Gardens and has been granted **the Award of Merit by the R.H.S.**

Used in the Royal Zoological Society's Gardens and Wisley Gardens.

TRANSPLANTING *SWEET PEAS*

BY this time, all autumn sown sweet peas—even in Scotland—should be in their permanent flowering quarters, but there are still many who have yet to transplant their spring sown plants from the pots or boxes. Although one should endeavour to plant out as early as possible, it is advisable not to transplant when the soil is in a wet and clingy condition, but to wait for a few fine days to dry the surface.

For ordinary purposes, that is, when a quantity of good blooms for home and garden decoration is required, 5ins. or 6ins. from plant to plant is ample, whether for rows or clumps. To meet the needs of exhibition culture on the "one stem" or "cordon" system, a space of 8ins. to 16ins. between each plant is advisable, varying the space according to the vigour of individual varieties. Briefly, the chief difference between "exhibition" culture and "ordinary" culture is that, in the former case, each plant is restricted to one, two or three main growths or leaders, the weaker varieties to one stem or growth, the more robust to two or three. All laterals are pinched or rubbed out when they are small; exactly the same procedure as in a tomato plant. Tendrils, too, are nipped off when quite tiny and so the whole energy of the plant is diverted to one, two or three growing points instead of, perhaps, a score if it were left to develop naturally. As may be expected, such plants with pruned and restricted growth, produce much larger flowers with longer stems than if left to their own devices to throw out a side shoot from the base of every left stalk in the natural manner. of course, there is the disadvantage of "exhibition" culture—apart from the extra labour and expense entailed—that a much smaller number of flowers are produced, even though they be of better quality.

To return to transplanting. The advice is often tendered that the roots of sweet pea seedlings should on no account be disturbed, and that the whole ball of soil surrounding them should be transferred intact. Provided the roots are not pot-bound and the potting soil is sweet, there can be no actual harm

ANTIRRHINUMS

IT'S only the fact that we grow and deliver especially good plants that we wish to advertise. The brightness, the long-flowering life, the wonderful adaptability of Antirrhinums (Snapdragons) are known to everyone. Although our plants are properly grown, transplanted, well rooted, hardened off, in all ways particularly good, as becomes a firm which reckon to do things well, the price is only

1/3 dozen. **3/6** 100.

THE NECESSARIES CO., 25, Edward Road, Balsall Heath, BIRMINGHAM.

in following this method. However, I must say I prefer to shake off gently the old potting soil and carefully disentangle the roots (if more than one plant is in the pot) before transplanting. If given a good watering the day before planting out, the potting soil usually comes away very readily in response to a gentle kneading with the fingers. Do not knock out all the pots or boxes at once, it is better to deal with a few at a time.

In planting, either a trowel or dibber may be used; get the roots well down and make the soil fairly firm round them. During a dry spell, a watering may be necessary immediately, but this should not be overdone and the hoe should be run round the plants the day following, to prevent the surface "caking." Until they begin flowering, watering should be avoided as far as possible and reliance placed rather on fairly frequent shallow hoeing to conserve the moisture in the soil.

Support should be given the young seedlings immediately they are transplanted.—S.

SPECIAL CUP FOR PEONIES.

MRS. EDWARD HARDING of Burnley Farm, Plainfield, New Jersey, the well known authority on garden peonies, has presented to the Royal Horticultural Society a sum of money which is to be devoted to the provision of three cups, one of which will be offered for award in each of the years 1926, 1927 and 1928, at one of the Society's fortnightly shows. The competition will be open only to amateurs, and exhibits must consist of three flowers of each of six varieties of peonies. Flora medals in silver-gilt and silver will be offered by the Society as second and third prizes respectively. This year the competition will take place on either June 1st or June 15th, according to weather conditions, and entries must reach the Secretary, R.H.S., Vincent Square, S.W.1, not later than by the first post on the previous Wednesday in either case. The decision as to the date of the competition will be made on or before May 22nd, and a card will be sent to all who have written to ask that the notification should be sent to them.

NOTES ON PRIMULAS—II

LET me now describe my experience of a few individual plants. Some may be uncommon or not in commerce, but they may be of interest to some readers all the same. I shall take first of all the capitata group, with such species as capitata, pseudo-capitata, denticulata, Mooreana, sphærocephala and cashmeriana, all related and all with tight, flat heads of tubular flowers—these descriptions may appear to be exiguous, but my object is not to describe plants but the conditions under which they grow. Now in this part of the country, eastern Scotland, and elsewhere, P. denticulata and its white form alba is extremely popular in cottage gardens; indeed, I have seen a bed 12ft. by 6ft. in full sun in a cottage garden in a village near Perth absolutely smothered in its deep lilac flowers. It often happens that what is a success in a cottage garden is often not so good elsewhere, but I have never known denticulata fail as long as the soil is not too poor and not too dry. It is certainly better in cultivated ground; in fact, this is the case with all primulas other than the candelabras, if they are to be treated as perennials.

A pair which like very similar conditions are P. sikkimensis and P. secundiflora, with drooping bell-shaped flowers on a fairly long tube. The former is citron yellow and the latter a rose purple, almost a mixture between a purple plum and ruby port. Of the two I find secundiflora the more vigorous and the better doer. Once it is established it is prolific in the increase of its crowns, so I save no seed of it. I am a little doubtful of sikkimensis, for it is not such a sturdy plant nor so prolific in division. It is, however, a free seeder, and germination is excellent, though I find the seedlings liable to damping off unless pricked off when small. I am going to save seed for a year or two. They both respond particularly well to cool root conditions; otherwise ordinary treatment seems to suit them.

Probably the group that causes most heartburnings are the Muscarioides, of which the best known is P. Littoniana. This primula always creates a mild sensation at Chelsea with its tight spikes of flower, red in the bud and violet when fully out, like a miniature kniphofia in shape. Messrs. Oliver and Hunter showed a giant form last year that was a magnificent sight. This group seems to rot quicker than any other during the winter, and seed should invariably be saved. They should be treated as biennials. P. Littoniana itself has never survived after flowering with me, although two smaller species of the same group, P. deflexa and P. melanops, have; but they may be exceptions, owing to the hard cold of last winter, and I would never trust them. I am sure that with them good drainage is a necessity and I have found them succeed best when I have mixed my heavyish loam with a good proportion of peat moss litter to give it buoyancy. They are, however, all worth the little extra pains necessary for their well-being.

Another group about which really very little is known is the nivalis. Certain of them are undoubtedly very difficult, and probably Sir Isaac Bayley Balfour's theory that they are best grown in a rose-bed is correct; but three of them are not only fine plants, but prove the exception to the rule. These are chionantha, sino-plantaginea and sino-purpurea. Chionantha is one of the finest white primulas in existence and is always admired whenever seen with its milk white flowers; sino-plantaginea is always recognisable by its long pointed leaves, dark green above and very pale beneath, and deep purplish-coloured flowers. Sino-purpurea has rose-purple flowers of a good tone. The last two I find particularly resistant to rot at the crown so long as their withered foliage is removed. They increase with me. Of chionantha I have not had long enough experience, but I should say that it wants more depth of soil than most primulas and rich conditions, as long as the drainage is good. It is a luscious-looking plant, and, although it thrives, I look upon it with suspicion.

Two primulas that do extraordinarily well under quite ordinary conditions are P. Munroi, like an improved involucrata, with the same small, neat foliage and fine white flowers, large for the size of the plant; and P. Veitchii of the cortusoides section with large round rather hairy leaves and magenta flowers. Munroi certainly approves of a dampish atmosphere, but Veitchii can withstand far drier conditions and is surprisingly hardy and sturdy. I have it planted both in a fairly dry and in a fairly moist position, and the growth is about the same. I think, however, that it approves of a good depth of soil.

Last, I shall mention P. rufa, so close in appearance to P. Forrestii that I cannot tell the difference between them. On the other hand, the former is hardy with me and the latter I have killed several times. These big, rich, yellow-flowered primulas are odd in their requirements, for they grow on a big woody stem. What they like is a crack in a brick wall or rock, where they can send out tiny roots in search of water, while their woody rootstock sticks out into the air and likes to be kept dry. I have it planted at the bottom of an overhanging rock facing due south but partly shaded. Here it seems perfectly at home.

E. H. M. C.

Owing to the strike, the issues of May 8th and 15th were not published.

NATIVE PLANTS IN OUR GARDENS

BY DR. R. LLOYD PRAEGER.

NOWADAYS the vegetation of the most remote parts of the world is being brought to our doors—or to our borders and greenhouses rather—by explorers, and plants from Peru, Tibet, New Zealand and Caucasia jostle each other in our gardens. The gardening papers and the nurserymen's lists are full of the latest novelties from distant places—rhododendrons, meconopsis and whatnot—and our minds are set on all kinds of exotic treasures. We are, I think, inclined to overlook the great contributions which our own native flora has made to our gardens, and the influence which it has always exercised, and still exercises, over British horticulture. It may be of interest to consider what our gardens owe to our own plants, from forest trees down to alpines. One often notices a kind of unconscious prejudice among gardeners against native species. "Oh, that's only a wild plant" is sometimes said, as if being a native of Britain were a reproach; and I have seen a gardener's face fall when he was told that so-and-so, which he had been showing with pride, might be gathered on Snowdon or in Teesdale. This mistaken idea is not shared by the true gardener, to whom a plant's beauty and grace are the things that matter most and not the country of its origin.

To begin with the biggest things which our country yields: what would our parks and woodlands be without oak, ash, elm, beech and Scots pine? All are native with us, the first three being widely spread in the British Isles, while the last is essentially northern and the last but one essentially southern. To these we may add lime, birch and alder. Among the smaller trees some have yielded a variety of beautiful or quaint garden forms, such as red, pink or double hawthorn, double cherries, the different forms of yew, and the remarkable range of varieties yielded by the holly; while others, again, such as the arbutus and the various species of sorbus, are used as decorative trees in their natural wild form. The many native shrubs found in our gardens may likewise be divided into two groups according as they are mostly used in their natural form, or in some "improved" variety which enhances their value for garden purposes. Among the former are the spindle tree with its lovely pink and orange fruit; the shrubby cinquefoil, one of the rarest of British shrubs; the honeysuckle; the two daphnes, Mezereum and Laureola; the sea buckthorn with its silver foliage and orange berries; and the parasitic mistletoe, always an object of interest in the garden. The gorse, on the other hand, is best for the garden in its double form; the broom in its parti-coloured Andreanus variety, whose brown and gold flowers have given rise to a numerous family of other handsome garden forms. Of the many native roses, the most valuable parents have been Rosa spinosissima and R. arvensis, from which the Scotch and Ayrshire roses have been produced respectively. Our native ivy haunts the garden in half a hundred leaf forms and variegated forms; the guelder rose is mostly grown in that curious variety, the snowball tree, in which only those barren flowers are produced which normally occupy the edge of its flat panicles of bloom. The elder yields cut-leaved and golden-leaved forms well known in our gardens; and privet is valuable in its golden and silver variegated varieties.

AN OFFSPRING OF THE NATIVE GIANT BELLFLOWER.

THERE ARE FEW OF OUR NATIVE PLANTS WHICH ARE SO EFFECTIVE IN THE GARDEN AS THE FOXGLOVES.

A fair number of native plants go to enrich our herbaceous borders. Thalictrum minus and its allies, the meadow-rues, are well worth growing for their delightful foliage, though the flowers are inconspicuous. The native globe flower, Trollius europæus, is as handsome as any of its Asiatic relatives. The red campion, Lychnis diurna, in its double form is very effective. The mallow family offers us the great tree mallow, Lavatera arborea. A

Digitized by Google

well grown plant of the form with variegated leaves in a sunny corner at the back of the border forms a striking feature. The meadow cranesbill, Geranium pratense, is a very fine thing, with purple or white flowers, double or single. The black vetchling, Lathyrus niger, makes a handsome upstanding clump. Few border plants have more handsome foliage than the dropwort, Spiræa filipendula, and its red-tipped buds and creamy flowers are good also. The yarrow, Achillea Millefolium, is effective in its red-flowered form; and I must confess to a great liking for the saw-wort, Serratula tinctoria, whose neat habit, deeply cut foliage and small thistle flowers combine to give a very pleasing *ensemble*. Among the British bellflowers, all of which are pleasing, the best are the tall Campanula latifolia, the giant bellflower with tall spikes of pale blue flowers, and the dwarf clustered bellflower, C. glomerata with deep blue heads of bloom. Of the latter there are several varying forms. Two of our native primulas, the primrose and cowslip, are largely represented in gardens. The former yields beautiful and favourite double forms—white, yellow, lilac and deep crimson—and it is curious that while the typical plant is so easy in cultivation (save on a limy soil), some of its offspring, such as Pompadour and Miss Massie, are cantankerous and exacting to a degree, and a well grown group of one of them is the pride of many a gardener's heart.

THE NODDING GLOBULAR HEADS OF TROLLIUS EUROPÆUS, THE NATIVE GLOBE FLOWER.

There are plenty of lovely single forms as well as double, and also the quaint hose-in-hose varieties. Then primrose and cowslip have combined in some way not altogether clear with their ally the oxlip (P. elatior) to produce the beautiful series of crosses that are collectively known as polyanthus. The genus primula is, indeed, one of the most important native contributors to our gardens.

There are a good many other plants of border type—that is, large or rather large perennials—which are on the whole more suitable for the wild garden or the woodland. One may instance the hellebore (H. fœtidus) with its green flowers in midwinter, an excellent shade plant; the favourite columbine, lovely in the woodland; the musk mallow (Malva moschata) and a few cranesbills, such as Geranium sylvaticum and G. phæum; that old fragrant favourite the woodruff, Asperula odorata; the tall, graceful valerian (V. sambucifolia) for a damp place; the nettle-leaved bellflower, Campanula Trachelium; the ever-welcome foxglove, purple and white; some of the spurges, such as E. hiberna; and among monocotyledons the shrubby butcher's broom, Ruscus aculeatus; the three native Solomon's seals, Polygonatum verticillatum, P. multiflorum and P. officinale, all most graceful plants; and that weird plant, Paris quadrifolia.

(To be continued.)

THE DRY SUNNY BANK

THERE are many gardens in which can be found a hot, dry, sunny bank; and no doubt the owner has been put to some trouble to clothe it suitably. Imagine a slope facing due south, fairly steep, and composed of a light sandy soil. Obviously, this will not accommodate the general run of plants, and a selection must be made comprising those that will endure great heat and, possibly, drought. Those dealt with here can all be obtained from leading nurserymen, and they are, for the most part, inexpensive. Speaking broadly, they will all revel in the poorest of soils; and the hotter it is, the better they will thrive.

The bank can be greatly enhanced if a few rocks are "planted" in it; but this is *not* essential, as, indeed, we are not making a rock bank. However, even though unpretentious, it will be a thing of great beauty during the summer and autumn months.

The following plants are a few of nature's gems that will soon smother the bank: Verbena chamædrifolia (syn. chamædrioides). This trailing plant produces in profusion heads of vivid scarlet flowers from June till late September. It roots freely from the joints of the stem, and is said not to be hardy. However, it recently withstood twenty degrees of frost here in Taplow, Bucks. Many people have, no doubt, been dissuaded from growing it by its so-called "tenderness," and the plant is, in consequence, too little grown.

A GLOWING COLONY OF SEEDLING AUBRIETIAS ON A DRY SUNNY BANK.

Among the aubrietias, which are really all suitable, are Fire King (crimson), Peter Barr (purple), J. S. Baker (violet blue with a white eye) and the old Dr. Mules (deep mauve). These will all rapidly clothe a bank, and one would think that they would flower themselves to death. Year in, year out, they produce masses of brilliant colour from early April to late June.

Next, we have two convolvuluses.

Digitized by Google

The first is C. althæoides. This rapidly growing plant is sometimes too rapid, but is, nevertheless, a very beautiful plant. The grey foliage is very finely cut, and flowers of a beautiful rosy pink are produced *ad infinitum* throughout the summer. The other convolvulus is C. mauritanicus; it is like the former, in that it is a trailer, but the flowers are of a lovely blue shade and produced in masses; it is also an excellent companion to Verbena chamædrifolia.

The helianthemums (sun roses) provide us with a wealth of material from which to choose. They are all evergreen, dwarf and somewhat shrubby, and give unlimited supplies of flowers from May onwards. The different varieties catalogued by nurseries reveal the following shades: rose pink, crimson, orange, yellow, terra cotta, white, etc.: double varieties are available, but, personally, I dislike them.

The genus cistus will give us a fine selection, and the species selected here are all no taller than 3ft. C. algarvensis has rather pretty foliage, grey in colour, and the leaves are quite small. The flowers, which are plentiful, are bright yellow, with a chocolate maroon centre. C. corbariensis makes a dwarf, rounded bush, and smothers itself with white blossoms. C. villosus var. Sunset is a very showy variety with bright rose-coloured flowers. These cistuses have the distinct advantage of reaching maturity in two or three years.

One of the most suitable of plants is Mesembryanthemum falciforme. A rapid grower, it is, unfortunately, not quite hardy except in favoured situations. It produces a wealth of glowing crimson flowers in July and August.

Another real gem is Alyssum saxatile var. citrinum. This beautiful plant produces "seas" of lemon yellow flowers in May and June. The variety compactum has golden yellow flowers; and Alyssum sax. fl. pl. has miniature double golden flowers. Besides the above mentioned, the following are all very suitable:

Achillea tomentosa, 4ins., yellow.

Achillea ageratifolia, 6ins., white.

Antirrhinum Asarina, creeping, with lemon-coloured flowers.

Arabis alpina superba, 6ins. white.

Cerastium Biebersteinii, 6ins. soft grey foliage.

Cheiranthus Allionii, 9ins. orange.

Hypericum fragilis, 3ins., yellow.

Iberis sempervirens var. Snowflake, 9ins., white.

Œnothera missouriensis, a beautiful prostrate plant, with enormous yellow flowers.

Saponaria ocymoides, 9ins., pink.

Sedums in variety.

Thymus Serpyllum coccineus, 1in., crimson.

Thymus Serpyllum albus, 1in., white.

Thymus citriodorus argenteus, 12ins., variegated foliage.

Thymus lanuginosus, 2ins. grey foliage.

Zauschneria californica, 15ins. scarlet.

Tunica Saxifraga, 6 ins., pink.

The following is another list, this time of annuals, that will succeed in a hot, dry position:

Sedum cœruleum, 4ins., blue.

Dimorphotheca aurantiaca, 9ins. white-orange.

Phacelia campanularia, 3ins., blue

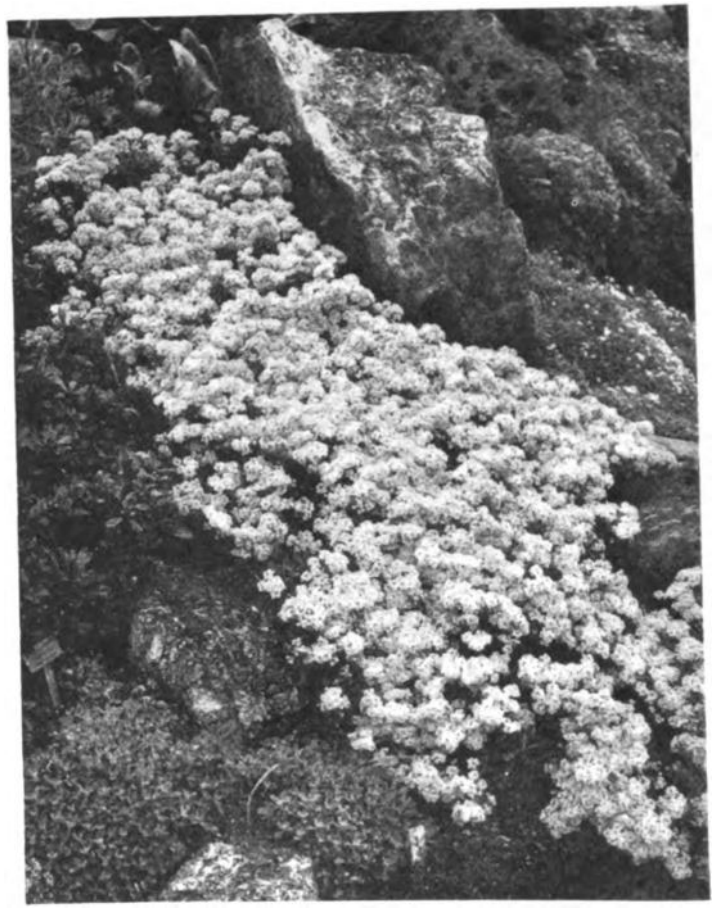
Phlox Drummondii, 12in., various.

Convolvulus tricolor, 12ins., blue.

Leptosiphon hybridus, 3ins., various.

Nasturtium and coreopsis vars.

JOHN BIRKENHEAD.



A FLOWING DRIFT OF THE FINE ROCK MADWORT, ALYSSUM SAXATILE.

SHRUBS FOR WALLS

BY W. J. BEAN.

(*Continued from page 267.*)

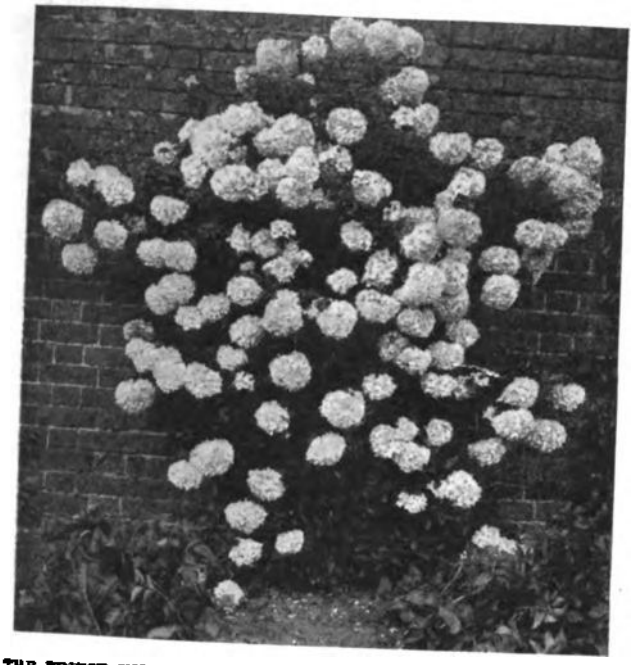
IN spininess of branch and shape of leaf, RIBES SPECIOSUM bears a resemblance to the gooseberry, but the flowers are very different and, indeed, the most beautiful of all this group of ribes. They open in April and May and are borne very profusely in pendulous clusters beneath the branches. They are rich red, tubular, ½in. long, with the equally highly-coloured stamens protruding ¾in. from the tube. This is a very attractive plant for a wall 8ft. or more high, but it is hardy enough to withstand all but the very hardest winters. An undoubtedly tender kind needing a wall is R. viburnifolium, chiefly interesting for its resinously scented leaves. It is evergreen, while speciosum is deciduous.

ROSA.—I will only concern myself here with a few of the tender hybrids and species of rose, such, that is, as need or thrive best on walls. The numerous varieties of garden origin that can be used as climbers form of themselves alone a subject for discussion.

The true Macartney rose, R. bracteata, makes a handsome wall plant, with its richly lustrous green leaves and its fragrant white flowers 3ins. or 4ins. across. Near London it is of no use trying to grow it in the open ground. It is evergreen and flowers from June until the frosts come, although never, so far as I have seen, bearing a great crop simultaneously. For a lofty, sunny wall, the lovely yellow banksian rose may be recommended for the south of England, but even in the sunniest localities it does not rival the wonderful displays seen in the south of France and in Italy. The rare and difficult hemisphærica (sulphurea), can only be grown with success on a wall, as Canon Ellacombe used to have it at Bitton, where its heavy, pendulous, very "double" flowers of a soft sulphur yellow, made a fine show every summer unless spoilt by persistent wet. A somewhat similar rose with a deeper yellow bloom, but held up more or less erect, is the "Persian Yellow," a form or hybrid of R. lutea, with double flowers. R. lævigata, known as the "Cherokee rose," but really a native of China, and a hybrid between it and R. Banksiæ called Fortuneana, are both handsome, the former with large single white flowers, the latter with double ones. The beautiful "Anemone," with large single flowers of an exquisite blush colour, is a hybrid from lævigata with some form of R. indica.

SCHIZOPHRAGMA.—S. hydrangeoides, as its name implies, bears a strong resemblance to the climbing Hydrangea petiolaris, which has, as a matter of fact, very often been grown as schizophragma. There is one clear distinction between the two genera in the bracts of the sterile flowers being usually four or five in hydrangea, but solitary (and much larger) in

Digitized by Google



THE FINEST VIBURNUM FOR A WALL, V. MACROCEPHALUM.

schizophragma. There are two species, the other being S. integrifolia, a native of China, S. hydrangeoides coming from Japan. Of the two, the Chinese one is the more ornamental, the bracts, at first cream-coloured, then white, being sometimes 3½ins. long by 2ins. wide; they hang downwards and many of them come on each flower truss. Seen when in flower, it is very striking, but it needs to attain a certain age before it blossoms freely. It requires a wall to bring out its best qualities, as does S. hydrangeoides also, although rather the hardier of the two.

TRACHELOSPERMUM.—The better of the two cultivated species of evergreen climbers is T. divaricatum, which has for many years been grown on a wall at Kew and, in some seasons, is covered with its creamy white, fragrant blossom, not unlike that of the better known T. jasminoides. This also grows healthily on a wall, but rarely flowers well; never so freely as in a cool greenhouse where it has long been grown for its fragrance. Wilson found, and I think introduced, other species, but I have not learnt that any have flowered.

VIBURNUM.—As a flowering shrub the finest viburnum for walls is V. macrocephalum. Although it is nearly hardy it never makes so fine a display in the open as on a wall. Naturally it is one of the most vigorous of its kind. Fortune, who introduced it, saw plants 20ft. high in China. The flower heads resemble those of a hydrangea, being composed entirely of sterile white flowers, each 1in. wide, the whole forming a globula truss 6ins. or more wide. It blossoms in May and June.

The now well known V. rhytidophyllum is hardy enough, but is a striking wall shrub, where I think it flowers and bears fruit more freely than it does in the open ground, and never seems to shrink into itself nor look so unhappy as it does in bitter wind or frost in an unsheltered position. The oval fruits which become red and finally black, are very handsome in the former state.

VITEX AGNUS-CASTUS.—It is curious that this shrub, introduced from southern Europe over 350 years ago, is so rarely seen. It needs a place on a wall, but this it well deserves, for its foliage is handsome and it blooms as late as September and October. The leaves are made up of five to seven radiating leaflets, each 2ins. to 6ins. long; and the flowers, which are pale violet and fragrant, come in racemes 6ins. or more long at the end of the season's shoots. It has to be pruned back every winter. It should be given a sunny spot and a space at least 10ft. square. It belongs to the verbena family and the leaves and young shoots as well as the flowers are scented. (Figured in THE GARDEN, November 11th, 1911.)

VITIS.—Most of the wild species of vitis are perfectly hardy and are well suited for pergolas or for climbing over trees. V. Coignetiæ (sent out from Waterer's nursery at Knap Hill many years ago and still often grown under the wrong name of V. Thunbergii), is one of them, but it is sometimes grown on walls for the wonderful crimson colour of its leaves in autumn, which seems to develop more richly there. The leaves of wall specimens, too, appear to grow larger and are frequently 1ft. wide, when the soil is rich. Still a wall is not really necessary for it.

It is not necessary in these days to say anything of the old V. inconstans, or Ampelopsis Veitchii, as it is so often called. Although it may be over planted in some places, it is a wonderful climber for town houses. But V. Henryana must be mentioned as being of the same type and as being especially suited for north walls, where the silvery and pink variegation of its leaflets is better developed than on a sunny one. Another of the same section of the genus is V. himalayana, a self-clinger, like the two just mentioned, whose leaves, made up of three leaflets, turn a rich red in autumn. Beautiful in a different way are V. heterophylla and its var. humulifolia, their chief attraction being the porcelain blue fruits. I have never seen this so fine as at Sion House one late summer day many years ago. Here it was growing in full sunshine in a border 1ft. to 2ft. wide, at the foot of a vinery wall, which it covered with its leaves and brilliantly coloured berries. I think its warm position and restricted root space explained its success.

The remarkable vine, V. megalophylla, which Wilson introduced from western China, we find will only keep in vigour on a wall, although it did very well on a sunny slope in the Coombe Wood Nursery, growing up and clothing a stout post 15ft. high. Its enormous, doubly pinnate leaves from 1½ft. to 2ft. long, distinguished it from all the other vines we can grow.

WISTARIA.—The common W. chinensis is a plant of remarkable adaptability. I do not know the maximum limits of the space it is capable of occupying on a wall, but I suppose 200ft. to 250ft. lengthwise is a moderate estimate. On the other hand it may, by pruning, be kept indefinitely as a shrub a few feet high, yet flower equally well under both conditions.

THE ORNAMENTAL SCHIZOPHRAGMA HYDRANGEOIDES DRAPING A HOUSE WALL.

Digitized by Google

The less common W. multijuga (whose proper name is W. floribunda macrobotrys), as well as the white and other forms of it, are not so well suited for walls and are better trained so that their racemes, often 2½ft. to over 3ft. long can hang free and untrammelled, such as on a lofty pergola or special overhead framework. When once these wistarias have reached their allotted space, the long growth they make annually should be shortened back to, say, a foot in length during the summer, and again in winter to within a few inches of the older wood. They produce their flowers from the basal buds.

The comparatively new and still rare W. venusta, as at present represented in cultivation, has white and often partially "double" flowers. It is quite a promising climber, well distinguished from the other two by its persistently downy leaves.

NOTES OF THE WEEK

AN ALPINE BANK.

A SHARP fall in the level between one piece of ground and another — how familiar a feature is this in the garden, and, alas! how seldom is its pictorial possibility recognised and the best made of the gift that Nature has placed in our hands. Far, far too often the sharply sloping bank is laid down in turf; turf that is never satisfactory, always looks stilted, and is the source of endless trouble in the continuous clipping that it entails at the busiest times in the year. If the fall is not too sudden, glorious banks of colour can be ensured during summer by the use of trailing annuals, such as verbenas or petunias, but these, after all, are only a temporary measure,

A FLORIFEROUS ROCK BANK AT THE BASE OF A WALL WHERE THE GROUND FALLS FROM ONE LEVEL TO ANOTHER.

and the ground looks very barren during the winter and spring days.

The alpine bank is the solution that gives the greatest amount of variation and interest, not only in the summer when all the garden is gay, but in winter and spring as well. In the former season a well planted bank is full of charming contrast by reason of the varied types of foliage that it contains, while in frosty periods, with every leaf outlined by a hoary margin, it becomes a veritable fairyland of wonders.

And then the spring. Long before winter has relaxed its grip the writing appears upon the alpine bank. A greening shows that draws one's attention. Odd crocuses, that have crept into the soil no one knows how, peep out their vivid gold here and there and draw us still closer to appreciate their early appearance. And then one sees that those invaluable "common" old flowers, the single white arabis and various aubrietias, are busy upon the work of bud making, the former boldly pushing forth the tips of its white petals, the latter yet but hinting at the glowing purples and soft mauves they contain. Cheek by jowl with these are silvery masses of white cerastium, effective all the year round, but never more beautiful than in early summer when smothered with their satiny white, starry flowers. Then, again, big tufts of Megasea saxifrage, leaves turned to a dull coppery red and preparing their great panicles of rose red blooms.

But let us push the clock forward a little and look at the alpine bank when in the zenith of its flower beauty. Phlox subulata in every imaginable shade of pink and mauve and snowy white is falling in cascades, aubrietias are sheets of glory, royal purple and deep pink, pale mauve and indescribable shades of blue lavender. Perennial candytufts are sheets of undefiled snow, golden alyssums are showers of gold, dwarf lavenders are preparing a feast of fragrance, while dianthi, in countless species, are budding towards perfection. All of these are simple ordinary flowers it is true, but wait until you have seen the united effect of their "commonness" before you pass your verdict. It is their very commonness that is one of their greatest virtues. For, once planted, they just go on happily for years, without attention or further care.

Would you have something a little more choice than all this? It is quite easy to accomplish. Set apart a small portion of your bank and build it up into a steep façade, with pieces of rock of moderate size. A fair amount of rock will be required, for the pieces must be wedged closely together, almost like dry walling, packing the interstices tightly with fibrous loam. The aspect must decide the nature of the plants to be grown, but here is an ideal home for any crevice-loving alpine, and many of the most difficult and choicest species can be grown to perfection. This façade should, in most cases, form but a small part of the alpine bank, and the greatest area should be occupied by those vigorous hardy long-lived "common" old plants with their far-flung masses of colour which adorn the bank for many weeks—H. W. C.

A LITTLE-GROWN SHRUB.

Bignonia capreolata.

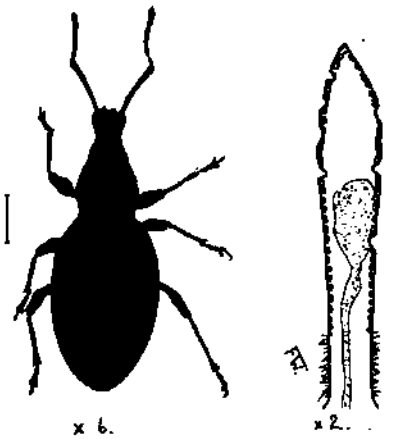
THE bignonia is a most graceful plant, and can be trained against a south or west wall. Our bignonia is a large shrub and grows against a south-west verandah and throws out long, elegant sprays with orange-red, bell-shaped flowers and heart-shaped, oblong leaves. Before knowing much about this shrub I treated it very badly, cutting it down when it should have been left alone. It seems quite hardy, but when the frost comes the leaves shrivel up, without, however, spoiling the vitality of the plant. I took various cuttings, and they strike very easily in pots of mixed earth and sand in a cold greenhouse. It is certainly well worth growing, but I have not seen it in any list, so perhaps it can only now be found in really old gardens like ours. A friend remembers seeing it grow many years ago near Honfleur in a big garden there. The bignonia is very useful for decorative purposes, having such long, graceful sprays. It seems a pity it is not more generally grown.—S. JENAM, *Plymouth*.

RHODODENDRON ROTUNDIFOLIUM.

THE pink, open, bell-shaped flowers and the peculiarly rounded, somewhat heart-shaped leaves cause this species to stand out in a marked manner among rhododendrons. Many years ago we purchased a plant from Messrs. J. Veitch and Sons, probably one of the first batch raised from seed sent home from Szechuan by Wilson. Planted in what was previously old pasture and partially shaded by tall trees and sheltered from draughts by walls, it made good growth, and both flowers and foliage were above the average size. Flowering freely, it was much admired, and became a pet plant. That, perhaps, was its undoing, as it was decided that the stock must be increased; consequently, its lower branches were layered, and when the layers were removed the cut ends attached to the parent plant remained in the mulch of rotten leaf-mould. Soon after the plant began to die back branch by branch. Did the mycelium of some wood-destroying fungus obtain a footing through the cut ends? This may possibly have been the case, and it is advisable after lifting layers to cut away the stumps cleanly and tar heavily.

Removal to a new site—carriage exercise—was tried without improvement, and lastly the remaining branches have been bent down and layered. Fortunately, we have other layers and seedlings growing on, among the latter some with foliage differing considerably from the type, probably of hybrid origin. In Cornwall some very fine specimens of this species have been recorded; there is also one or more thriving splendidly in the woods at Wakehurst Place, Sussex. Judging from the best examples known,

Digitized by Google



The Weevil Pest of Saxifrages, Otiorrhynchus rugifrons, magnified six times.

Leaf of Saxifraga Hostii attacked by adult weevil and mined by its larva.

this species would appear to like more shade and moisture than the majority of the genus. —J. COMBER, *Nymans*.

A CREEPER WITH A CURIOUS HISTORY.

IN a little unheated greenhouse a creeper with a rather curious history is flowering in a Devon village not far from Exeter. Some thirty or so years ago the seed was sent back from Australia by a lad to his mother, who, having no garden, laid it aside and it was forgotten, till it was found during a turn out about three or four years ago. The seed was sown and germinated, and in due course the plant bore a single flower. The year after there were a few more and this year the plant is covered with blossom.

It appears to be a species of stizolobium, so called from its prickly pods, and belongs to the Phaseoleæ, a branch of the pea family. It has large dark green leaves of elegant shape and panicles of the most exotic looking flowers. Each individual flower is very long and thin, reminding one at first sight of the Glory Pea (Clianthus puniceus). Of the darkest purple colour, so dark, in fact, that the flower appears to be quite black, the lower lip is decorated with a long, bright yellow blotch. It makes one wonder why Nature chose such curiously contrasting colours with whic.. to adorn this flower, whic.. has the further peculiarity of shyly hiding away behind the leaves. It has a relative in Brazil which goes by the name of mucuna and is called cow-itch by the Brazilians because the prickly pods irritate the cattle. We are at the moment waiting anxiously to see whether the creeper will set any seed this year, so that the species of stizolobium may be determined.—EDWARD CAHEN.

A WEEVIL PEST OF ALPINE PLANTS.

IT is desired to draw the attention of those interested in the cultivation of alpine plants to a weevil pest which may be called for convenience the "saxifraga weevil" by reason of the preference shown by this pes for these plants. The species, Otiorrhynchus rugifrons Gyll., is closely allied to the vine weevil (O. sulcatus F.), which is also a pest of alpines, the larvæ of both species often occurring together at the roots of the same plant. The preferred hosts are saxifrages, lewisias and primulas, although many other plants are attacked. The saxifraga weevil is really a coastal species, but is now prevalent in many inland districts and does a great amount of damage both in the larval and adult stages. An account of the life-history appears in the *Entomologist's Monthly Magazine* for December, 1925 (Vol. LXI, pages 273–276). The adult weevil is found in May and June crawling over saxifrages and other plants, on the leaves of which it feeds, choosing the edges and biting out portions, the attack resembling that of the bean weevil (Sitones lineatus L.) on broad beans and peas.

The eggs are laid singly either in the junction between leaf-stalk and stem or on the upper surface of the leaf. On hatching, the larva is a legless, rather wrinkled, curled creature which either makes its way directly to the roots or burrows into the leaf, in which it feeds, making a "blotch" mine. It is not known whether the mining habit is an established character. It feeds on the soft parenchymatous tissue between the upper and lower epidermis, eventually tunnelling down the petiole and stem through which it bites in order to reach its ultimate goal, the roots. When the larva is below ground it is possible to pull several of the rosettes away, the underground stems and main roots being partly or completely severed.

The larval stage is found in the soil for several months, usually from July to the following February, when it pupates in an earthen cell surrounding the food plant, and the adult weevil emerges in May and June.

Many species of saxifrages are chosen for oviposition, and it was found at Wisley that eight species are particularly favoured by them. Seven species belong to the Euaizoonia section, *viz.*, Saxifraga Aizoon, S. Cotyledon, S. Hostii, S. lingulata and its varietal form lantoscana, S.crustata and S. cochlearis, and one to the Robertsonia —S. cuneifolia.

Remedial measures consist of (1) hand-picking the larvæ during repanning and (2) in the case of plants growing in the open garden, the injection of carbon bisulphide in the soil. This latter operation should be performed in dry weather, preferably in July and August, care being taken that the liquid, which is highly inflammable, does not come into direct contact with the roots. A hole is made in the soil surrounding the attacked plants by means of a wooden skewer and the liquid, used at the rate of 1 oz. to the square yard, poured in, closing the hole with a stone or a piece of clay to prevent the escape of the fumes. —G. FOX WILSON, *Wisley*.

[If readers are of the opinion that any of their alpine plants are attacked we would be pleased if they would forward infected plants for the identification of the pest.—ED.]

A CHARMING OLD FASHIONED GREENHOUSE SUBJECT.

Cotyledon Gibbiflora metallica.

A FEW weeks back the Editor asked for photographs and notes of old-time plants that are seldom seen to-day. Here is one such, though the illustration is far from doing justice to the plant, which belongs to the houseleek family and the natural order of crassulaceæ. It is when in flower that our subject is most attractive, the apricot-coloured little bells or cups being really beautiful when seen against the metallic-leaved tufts of foliage which constitute the make up of the plant. And the spikes of bloom are quite freely produced as can be seen from the illustration, to which must be added the further virtue of the flowers lasting in good condition over a long period. Moreover, this plant is simple to grow and requires but a low temperature to winter it safely—say about 40 degrees to 45 degrees. These excellent points should commend this plant to all, and particularly to those whose means and conveniences for plant growing are not of the most adequate. The time of flowering may be any time between Christmas and February—the strength of the plants and the heat they may have been subjected to during the summer accounting for the variation.

Respecting its culture, the present is the time to insert as cuttings some of the tufts of leafage with a portion of stem attached in very sandy soil—standing the small pots on a shelf in the greenhouse or frame until the pieces are rooted. Very little moisture will be necessary, but a thin shade is necessary until the new plants are self-supporting. Ample drainage is imperative at all times and the addition of old mortar to the loam used for potting is beneficial. Plants can be encouraged to fill any size of pot preferred, but a 7in. will be found to be a handy size for the greenhouse.—C. TURNER.

PLANT COLLECTING IN AUSTRIA

A NOTE ON THE GENESIS OF THE FLORA OF THE EASTERN ALPS.

BY PROFESSOR R. SCHARFETTER,
Of Graz University, Styria.

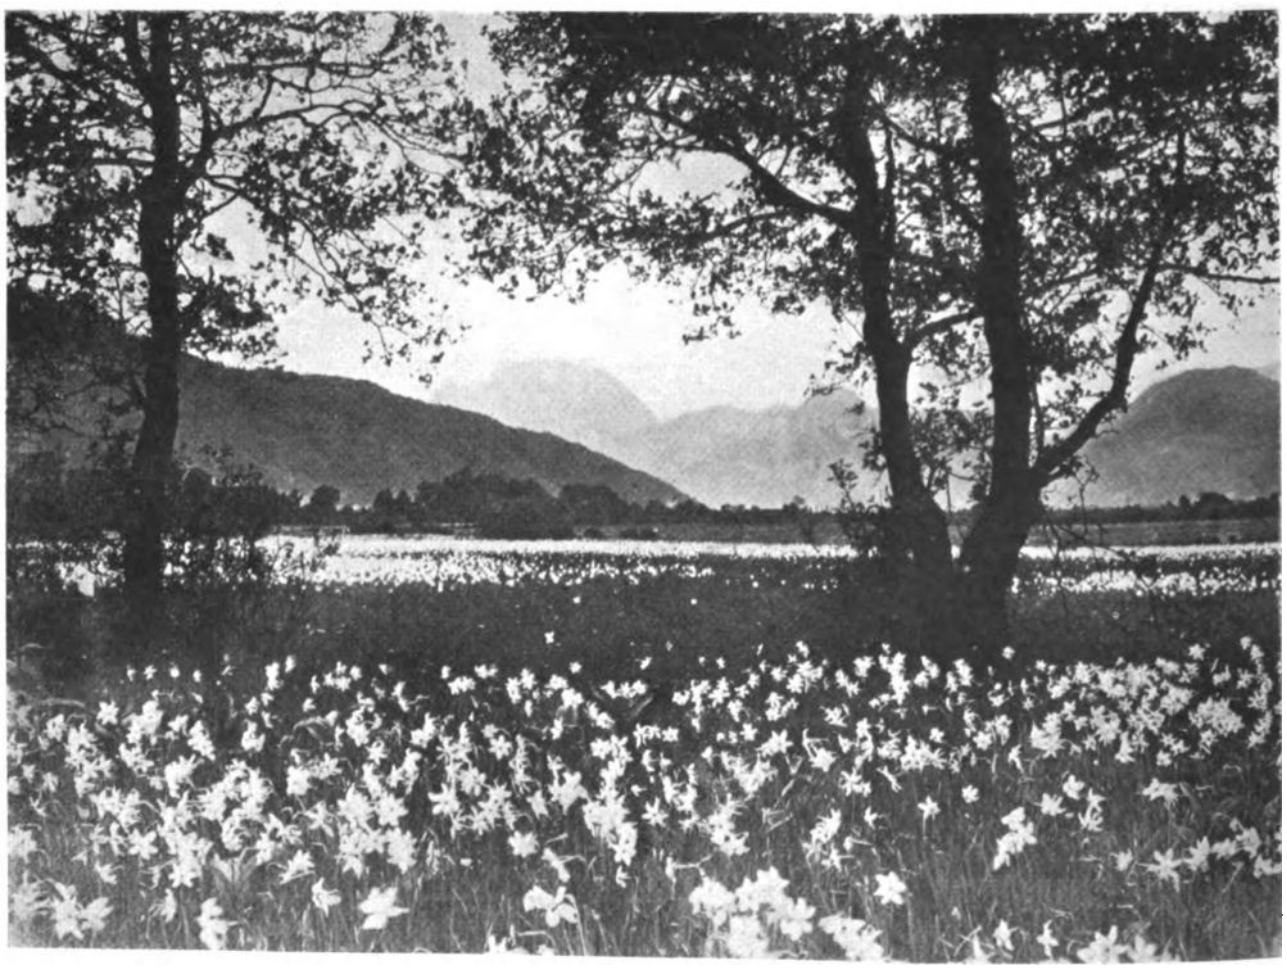
THE Alps are the barrier between three floral areas: South is the Mediterranean area, with shrubs like laurus, olea, Punica granatum, citrus, with bulbs like scilla, gladiolus, asphodelus, etc., and labiatæ and leguminosæ like cytisus, genista, rosmarinus, etc.; in the east is the extensive Hungarian plain with steppe vegetation originating in the Pontus steppe (Stipa Andropogon); and in the north is the home of the Middle European Baltic flora.

All three varieties of vegetation are to be found throughout the alpine valleys and on the lower slopes of mountains.

This is the reason why the flora of the alpine valleys is as varied and attractive as that of even higher mountains.

Following the emerald green waters of the Isonzo from the Monte Santo, near Gorizia, up-stream, Beck could observe the diminution of the Mediterranean and Illyric elements, so that these varieties are entirely lacking in the valley of Flitsch, where the most desperate fights took place in the late war.

	Mid-Europ. kinds per cent.	*Illyric kinds per cent.*	*Mediterr. kinds per cent.*	*Mid-Europ. alpine kinds per cent.*
Monte Santo	62.1	26.5	11.4	10.9
Tolmein-Schlossberg ..	71.4	14.6	4.4	9.6
Karfreit	44.3	19.8	2.8	33.0
Flitsch	71.3	12.5	—	16.2



A HOST OF WAVING NARCISSUS ANGUSTIFOLIUS IN STYRIA.

The proof of this statement is the flora of the province of Lower Austria, according to Beck v. Managetta:

Pontish flora	270 kinds ..	12 per cent.
High alpine flora	210 kinds ..	9 per cent.
Lower alpine flora	138 kinds ..	6 per cent.
Middle European flora ..	1,435 kinds ..	62 per cent.
Cultivated and foreign growth	256 kinds ..	11 per cent.
	2,309 kinds ..	100 per cent.

The two research workers, Kerner and Beck v. Managetta, who have made an exhaustive study of the invasion of eastern plants into the Danube Valley, maintain that this advance has always been going on, whereas a migration of plants in the opposite direction has never taken place.

The same applies to the southern Alps. Here, too, an immigration plant-herd ascends the alpine valleys.

You may gather in the basin of Gorizia, as the centre, the following Mediterranean plants: Adiantum Capillus-veneris, Ceterach officinalis; Asphodelus albus, Asparagus acutifolius, Quercus Ilex, Celtis australis, Galium purpureum, etc.; whereas the Illyric species, which may be found mostly up-country, are chiefly indigenous to the formerly Austrian province of Istria: Quercus lanuginosa, Ostrya carpinifolia, Prunus mahaleb, Colutea arborescens, Rhamnus saxatilis, Sesleria autumnalis, Linum tenuifolium, Ruta divaricata, Melittis Melissophyllum, Scabiosa graminifolia, Centaurea axillaris, C. rupestris, Lactuca perennis, etc.

This advancing of southern species northwards leads us to an important question—to the question, namely, of the periods of advance and the length of time involved. Beck has ascertained that a series of southern plants reappears in Carinthia, for which an immigration over the passes is utterly impossible, considering the climatic conditions of our times.

Digitized by Google

Given that the forest region was once 1,000ft. higher than to-day, which was the case in the interglacial period, when the passes were more practicable for the invasion of the Illyric species, this leads us to the supposition that a great number of Illyrian plants overstepped the limits at this time.

The original home of those remains which we find scattered over the eastern Alps was the upper Vintschgau (valley of the Etsch or Adige), near Glurns and Schlanders, with the centres of Bozen and Trient (Bolzano and Trento) for species like Ephedra distachya, Telephium Imperati, Astragalus exscapus, A. vesicarius, Dracocephalum austriacum; near Innsbrück, Stipa pennata, S. capillata, Ostya carpinifolia, Astragalus Onobrychis, Oxytropis pilosa, etc.; the Enns valley (centre Gröbming and Liezen), Narcissus angustifolius; and near Gresten and Scheibbs (centre St. Pölten, Lower Austria), Crocus neapolitanus; south of Baden, near Vienna, to the borders of the Schneeberg, Pinus nigra. One of the richest and most interesting homes for southern and eastern types is Peggau (north of Graz); there you find Moehringia Malyi, Alsine setacea, Thalictrum fœtidum, Alyssum transylvanicum, Anemone stiriaca and Geranium rotundifolium; also the Weizklamm (east of Graz), with alpine plants such as Primula auricula, Dianthus plumarius, Valeriana saxatilis, Carduus glaucus, and plants such as Philadelphus pallidus, Euonymus latifolius and Ostrya carpinifolia.

Besides the above-mentioned places of association of xerotherm (heat-loving) and alpine plants, there are many other places where they are to be found, chiefly in ravines—in the Inn Valley in the Austrian Tyrol in the Gail Valley and the Sattnitz in Carinthia, in the valley of the Etsch in the now Italian Tyrol, in the Isonzo Valley, the Save Valley near Ratschach (centre Cilli).

Chiefly in the central Alps, where the naked rock, with its varied chemical composition, is nearly bare of earth, there are the most favourable conditions for the largest number of different kinds, whereas on the contrary, humus, or turf covering, limits the varieties by giving the same living conditions to all.

Here, on the heights, which are free from humus, chiefly originate the contrast and difference between plants depending on limestone and those depending on silicates. Plants growing on lime are: Salix reticulata, Ranunculus alpestris, Papaver Sendtneri, Draba tomentosa, Arabis pumila, Soldanella minima, Achillea atrata, A. Clavennæ; plants which cannot thrive in lime are: Salix herbacea, Saponaria pumila, Saxifraga Rudolphiana, S. bryoides, Doronicum Clusii, etc. Most interesting is the statement that similar growing conditions produce parallel and closely related kinds in the silicate and limestone districts:

Plants which thrive in lime.	*Plants which do not thrive in lime.*
Gentiana acaulis	G. excisa
Achillea atrata	A. moschata
Rhododendron hirsutum	R. ferrugineum
Juncus monanthus	J. trifidus
Hutchinsia alpina	H. brevicaulis
Primula auricula	P. villosa
Ranunculus alpestris	R. crenatus
Dianthus alpinus	D. glacialis
Poa minor	P. laxa

Before continuing the history of the alpine flora, let me give a few examples of parallel forms, caused, not by the composition of the soil but by the respective height and by the climate. Vierhapper, who has made an exhaustive study of these facts, gives the following list of parallel forms of the same species, which follow each other vertically:

Lower area.	*Higher area.*
Rumex Acetosa, *L.*	R. arifolius, *All.*
Dianthus deltoides, *L.*	D. myrtinervius *Gris.*
Myosotis sylvatica (*Ehrh.*) *Hoffm.*	M. alpestris, *Schm.*
Solidago virga aurea, *L.*	S. alpestris, *Schm.*
Senecio Fuchsii, *Gml.*	S. cacaliaster, *Lam.*
Centaurea pseudophrygia, *C. A. Mey*	C. plumosa, (*Lam*) *Kern.*
Phleum pratense, *L.*	P. alpinum, *L.*
Avenastrum pratense (*L.*) *Jess. s.l.*	A. versicolor, (*Vill.*) *Fritsch.*
Trisetum flavescens, (*L.*) *R. et Sch.*	T. alpestre, (*Host*) *Beauv.*
Trifolium pratense, *L.*	T. nivale, *Sieb.*
Soldanella major, (*Neilr.*)	S. hungarica, *Simk.*

A CLUMP OF SAXIFRAGA PARADOXA AT FIFTEEN HUNDRED FEET.

Apart from the important effects of the ice age on the distribution of plants in the Alps, one must mention the exchange of plants between the extreme north (arctis) and our mountains. Driven southward by the pressure of ice from the north, arctic plants mixed with those of the Alps in the ice-free belt of central Europe. Later on, with the melting ice certain arctic plants advanced towards the Alps, while those of the Alps found their way to the north. That is the reason why the following varieties belong to both floral (arctic and alpine) regions: Ranunculus glacialis, Papaver alpinum, Cardamine alpina, Braya alpina, Alsine biflora, Dryas octopetala, Sibbaldia procumbens, Saxifraga stellaris, S. cernua, S. aizoides, Polygonum viviparum, and many juncus and carex species. Wettstein draws attention to the fact that all these arctic kinds, as is to be expected from their origin, like *wet and cold* places on the one hand, and glacier moraines on the other. No less striking is the fact that the arctic types, with few exceptions, are less conspicuous, and mostly smaller and less brightly coloured than the alpine types; for the pollination by insects plays a smaller part in the north, where insects are scarce, than in the Alps.

The Alps, then, can boast of a quite exceptionally rich flora, due to different causes. Differences of climate and rock play the most important part in giving richness to the alpine flora, compared with that of the plains. In the course of the historical development of the flora of the far north (arctic) and of the warm south and east (Mediterranean-Illyrian and Pontic), innumerable specimens of these varieties found their way to the Alps, where the varied character of the ground and the great contrasts of climate offered a home where all could survive.

WULFENIA CARINTHIACA IN ITS NATIVE HOME ABOVE PONTEBBA.

Digitized by Google

I have clearly shown where, in the Alps, the botanist may find the best places for collecting: that is, where lime and silicate meet; for example, the Inn and Drau Valleys (Innsbrück, Schladming, Villach), then the Wachau (Danube Valley between Melk and Krems), the Etsch, Isonzo and Save Valleys, on account of the invasion of neighbouring floras, and, lastly, Styria, Carinthia and Carniola, on account of the above-named tertiary relicts (centres mentioned above).

As a handbook for the determination of plants growing in the eastern Alps we recommend: Fritsch, "Excursions-flora von Oesterreich, as well as Hegi and Dunzinger, "Alpenflora."

In closing this note about alpine plants, I cannot conclude without reminding the reader that not only the beaten tracks of the Swiss Alps are worthy of being explored but that the eastern Alps furnish, indeed, a most attractive and successful hunting-ground as well as very fine scenery.

THE RHODODENDRON SOCIETY'S SHOW

CONTRARY to all expectations, the first Show of the Rhododendron Society, held at Vincent Square on Tuesday, April 27th, proved a triumphant success. No season could have been more against the success of a show of this kind, for the extraordinary warmth of February and March brought on rhododendrons perhaps more than any other flower, so much so that the original schedule had to be considerably enlarged, as many of the rhododendrons classed in the first schedule were completely over. Even the stormy weather of the previous few days had done surprisingly little damage, and it is safe to say that there has rarely, if ever, been such a colour display in a single show at Vincent Square.

Not only is the rhododendron difficult to illustrate, but it is equally difficult to describe. Those shown at Vincent Square included everything, from the tiniest dwarf to flowering branches of big tree rhododendrons, and every colour, from purest white through yellow and the whole gamut of rose reds and pinks to the pure blue lilac of Rhododendron Augustinii. The Rhododendron Society deserves every credit for its courage in holding a show devoted solely to these most magnificent of flowering shrubs, and also praise for the manner in which the Show was arranged.

The best large exhibit staged by an amateur was that of Lady Aberconway and the Hon. Harry McLaren, which gained the first prize of a challenge cup and silver-gilt medal. Possibly the most striking example of a rhododendron, to those who are unacquainted with any except hybrids, was shown on this stand. This was a bush of Rh. Williamsianum, about 2ft. in diameter, a most charming, low-growing species with bronzed young foliage and bell-shaped flowers of a soft rose colour. At the back of the stand were big clumps of Augustinii and yunnanense. Many fine hybrids were shown, among them the most noticeable were Soulking, one of Mr. Magor's raising, of a clear rose; and Alice × Aucklandi, very pale pink flushed with cream, in fine trusses of open flowers.

Mr. L. de Rothschild and Mr. A. M. Williams were bracketed equal second; the former showed chiefly hybrids of most excellent quality, among them being very fine forms of Loderi, Loder's White, and Fortunei × Thomsoni—a hybrid, by the way, that was shown on many stands, and has undoubtedly a great future in front of it, for the rose colour is generally clear and pure, and it is a good grower and perfectly hardy. Mr. A. M. Williams, on the other hand, showed mostly species, and certainly staged the best collection of the Triflorum series in the Show. This is of the greatest importance to the ordinary amateur, for of all species those centring around Triflorum, with their hardiness, quick growth and freedom of flower, will be the most likely to become every-day garden plants. The blue Augustinii and the pinkish white and blotched chartophyllum præcox were exceedingly fine. No third prize was given for the amateur exhibits, but Lady Loder and Mr. Barclay Fox were bracketed equal fourth. Lady Loder showed fine examples of the famous Leonardslee hybrids, with an enormous centre clump of the magnificent Pink Diamond, certainly the finest pink Loderi in existence; while Mr. Barclay Fox staged many of the really fine crosses which have been raised in Cornwall, such as the rich rose Cornish Cross and Penjerrick. So close were all these exhibits in point of quality that the judges must have had a hard task to decide the various points of excellence. Admiral Walker-Heneage-Vivian's exhibit, although it was not awarded a prize, was noticeable for particularly fine sprays of fragrantissimum and Falconeri.

Although the trade did not show so many species as the amateurs in their big exhibits, yet they managed to stage magnificent shows of hybrids. The one exception was Mr. Gill of Falmouth, who was awarded the challenge cup and silver-gilt medal for the best group of rhododendrons shown by a trade exhibitor, for he was able to stage not only hybrids but also numbers of species. Unfortunately, the space allotted to him was hardly large enough for the collection he had brought up from Cornwall, and consequently they were rather crowded; but on close examination an extraordinary variety of plants could be discovered. Probably the best forms which he showed were those of Augustinii, Aucklandi, Dalhousiæ, Keysii, Loder's White and orbiculare. They certainly showed excellent cultivation. Messrs. Wallace confined their fine exhibit mostly to hybrids of Messrs. Van Ness' raising. Many of them are undoubtedly exceedingly valuable garden plants of great hardiness, and yet with large trusses of fine colours. Red Emperor was certainly one of the best. This is No. 216, and is an improved Britannia, with a better shape of truss and the same pure scarlet colour. Among others were the Earl of Athlone, one of the richest reds in existence; and Mrs. A. M. Williams, a very pure rose, but, unfortunately, an

A GENERAL VIEW OF THE RHODODENDRON EXHIBITION.

Digitized by Google

exception, in that it is inclined to be tender. Messrs. Waterer, Sons and Crisp had a wonderful exhibit of their well known hardy hybrids, such as Alice and Corona. A big bush of Ragged Robin in the middle was much admired, but its rose colour is rather on the blue side for some people's taste. One of the most notable plants in the Show was their new hybrid, called Sir John Ramsden, a cross between Corona and Thomsoni. This is cream striped with rose, and is so striking that the raisers will undoubtedly have a great success with it once they are able to raise sufficient stock. Messrs. Slocock had a stand of hybrids in pots, mostly Aucklandi seedlings, but among them was a very fine Fortunei seedling of a good, but very pale, pink. Messrs Cheal also had hybrids in pots, and Messrs. Hillier young species rhododendrons of the latest sendings of Forrest and Kingdon Ward. Messrs. Veitch also staged many good hybrids.

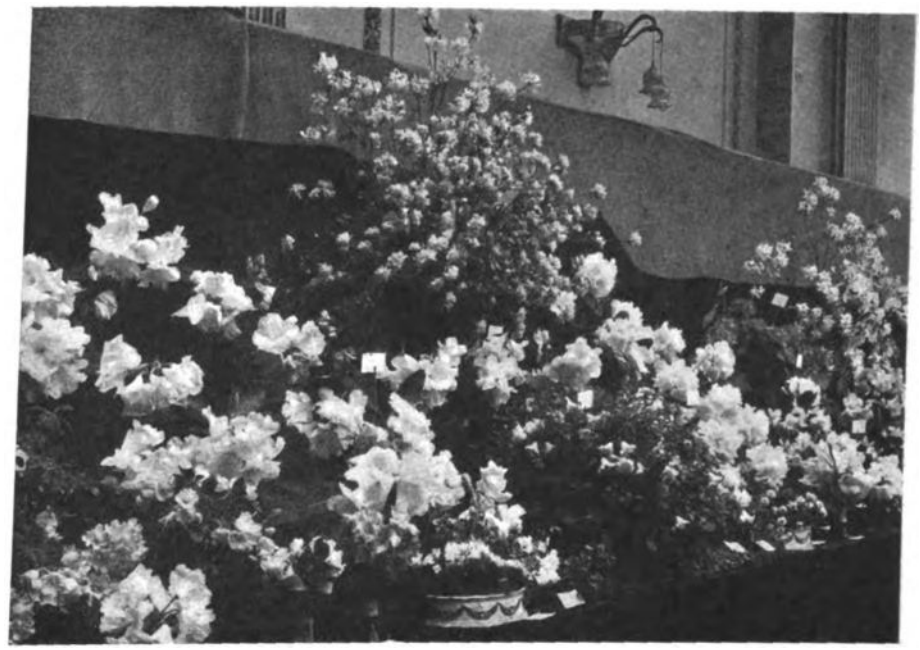
Messrs. Cuthbert were awarded a special prize for their magnificent show of Japanese azaleas. The colours were all very fine. Among them was one called Sunset, of a rose flushed with orange—an almost indescribable colour—but far ahead of all others. This is a cross between Hinodigeri and Kæmpferi.

The two great Dutch firms of raisers had small collections of their newest varieties. Those of Messrs. C. B. van Ness, although interesting and of good quality, had nothing better to show than their well known hybrids already to be found in many gardens, such as the Earl of Athlone, Britannia and Douglas McEwen. Messrs. Koster, in Mrs. Helen Koster, have a gem for those who like flowers with a big blotch. This has a very large, flat faced flower in a fine truss, the colour being white flushed with palest lilac and a big brown-crimson blotch. It is a most striking plant.

The special prize for the best plant in the Show was given to Lady Aberconway and the Hon. H. McLaren for the magnificent specimen of Rh. Williamsianum shown in their main exhibit, while the special prize for the best species was awarded to Mr. P. D. Williams for Forrest's form of Rh. decorum, a beautifully shaped flower of the softest pink.

FIRST-CLASS CERTIFICATE

RHODODENDRON HÆMATODES.—One of the finest of the brilliant red semi-dwarf species. It was introduced by Forrest in 1906. Shown by Mr. A. M. Williams, Werrington Park, Launceston.



A SECTION OF LADY ABERCONWAY'S EXHIBIT, WHICH WAS AWARDED THE CHALLENGE CUP.

AWARDS OF MERIT.

RH. ASTROCALYX.—A late introduction of Forrest's and similar to Rh. litiense, croceum and Wardii. The flowers are open campanulata, lemon yellow in colour, without markings. The leaves are dark green above and lighter below, of the shape of Thomsoni, but smaller. Shown by Mr. A. M. Williams.

RH. CROCEUM.—A fine species found by Forrest in Yunnan in 1913. The flowers and leaves are similar in shape to R. astrocalyx. The colour of the flowers is a good lemon-yellow, always with a crimson blotch at the base of the upper segment. Shown by Mr. A. M. Williams.

RH. GLADYS.—A charming cross between Rh. campylocarpum and Rh. Fortunei. The wide flowers, with wavy margins and of a fine pink, marked at the base with brownish-crimson, are freely borne on loose trusses. This is obviously a very floriferous hybrid and a valuable garden plant. Shown by Lord Swathling, Townhill Park, Southampton.

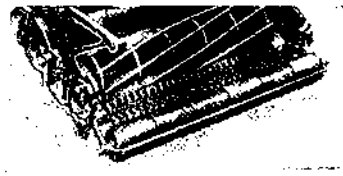
RH. MRS. A. M. WILLIAMS.—A fine garden hybrid with large flowers of a good rose, varied with a deeper shade. The buds are particularly brilliant in colouring. Shown by Messrs. R. Wallace and Co.

RH. SIR JOHN RAMSDEN.—A most distinct hybrid, with upstanding trusses of medium sized flowers of a blush pink with stripes of rose colour on the outside. It is very floriferous and will make a most valuable garden plant. Shown by Messrs. Waterer, Sons and Crisp.

LAWN SUNDRIES

THERE is, perhaps, no greater drawback to the appearance of a lawn than the overgrowing and tufty edges so often seen alongside paths and borders. The regular cutting and trimming of these is certainly a long and tedious task when performed with the old-fashioned hand shears and turf edging tool. It is now possible, however, for those of average means to obtain one of the new types of machine trimmers, the use of which will undoubtedly save much valuable time. One of the most up-to-date of these machines is that known as the "Stoakes" Edge Trimmer and Cutter. This is a combination machine which will perform the dual tasks of either trimming the grass or cutting and reshaping the edges. The cutting depth of the knives can be very easily regulated, and the whole machine is extremely simple to operate. With most of these machines a perfect edge can be obtained on any lawn, as fast as a man can walk. Another machine which is extremely useful is the "Ransome" lawn sweeper, which is rather similar in action to an ordinary mower, with the exception that it is fitted with a brush instead of a cutting cylinder.

For use on smaller lawns, an ideal cleaning tool is the "Springbok" Lawn Rake. This rake, having flexible pins,



A NEW TURF CULTIVATOR FITTED TO A LAWN MOWER.

does not catch in roots, etc., and will remove all leaves and rubbish without damaging the surface of the lawn. It is extremely useful for removing moss and dead grass without pulling up grass roots. It has the additional advantage of being very reasonable in price. The use of a spiked roller is also extremely beneficial to the surface of the turf. For ordinary hand use there is no better than the "Sarel," by means of which the largest green can be thoroughly treated in a very short time. The pointed spikes on the roller puncture the turf to a depth of about 1in. and, as the roller turns, form pear-shaped incisions under the surface which thoroughly aerate the subsoil without increasing the small hole made on the top. The "Atco" Turf Cultivator is also worthy of attention, inasmuch as it is intended for use with the famous mowing machine of the same name. It is fitted in front of the cutter of the machine and revolves at high speed when the machine is in use. By this means both mowing and aeration of the lawn are performed simultaneously. The number of makes of sprinkler is legion, and the discussion of their various merits is a subject which is, perhaps, better left to a more seasonable period. The presence of weeds on lawns is highly objectionable, and the question of how best to eliminate them

Digitized by Google

is a big one. Many people resort to the practice of introducing a killing agent to each individual plant. This is a somewhat tedious and dangerous task, inasmuch as the weed killer is usually highly poisonous and the application of it a very back-aching task. There is, however, an appliance, known as the "Success" Weed Eradicator, which simplifies this task immensely. It consists of a tube about the length of a walking-stick, which acts as the container for the killer. It is fitted at the lower end with a slender spring point, which is so arranged that, by simply stabbing the point into the heart of the plant, sufficient liquid is released to destroy it. It is simple to use, and weeds can be dealt with as one walks along. For those who prefer to uproot each individual plant, there are several types of extractors, most of which consist of a sharply pointed instrument which broadens out into a claw-shaped hook which catches round the roots as the instrument is pulled out of the ground. These can be obtained fitted on to an ordinary walking-stick, which does away with the necessity of constant stooping. For dealing with larger clumps of weeds or patches of bare turf, the "Atco" Company have devised a very ingenious tool which extracts weeds, etc., complete with roots, and can then be used for substituting fresh turf of exactly the same size into the hole made.

Particulars and illustrations of most of the various mechanical aids I have mentioned can be seen in the catalogues of regular advertisers in this journal, and the small trouble involved in sending for them is well worth while. J. W.

CORRESPONDENCE

PRUNING PHILADELPHUS.

SIR,—In your leader, issue April 24th, you refer to the pruning or rather thinning of a philadelphus plant and the remarkably fine result as regards subsequent growth and flowering. Some years ago I had charge of a large garden in which many plants, in several varieties, were extensively grown. A few grew, or rather existed, on a dry, low bank. As the bushes were so straggly I cut out many branches low down to induce a more compact growth. The new shoots came away much stronger than I anticipated and flowered very freely, indeed. Another bush had its top shoots only cut off, hedge-trimming fashion, result, more weakly shoots, flowers nil. Afterwards, the more favoured bushes were freely thinned and the results were equally gratifying, the individual flowers being larger also.—HANTS.

TREATMENT OF CAPE BULBS.

SIR,—You ask in THE GARDEN of April 24th, for your readers to give their experiences of growing tritonias, babianas, etc., out of doors. I have grown all these Cape bulbs for many years over here and found them easy. They like a light, sandy soil and a sunny exposure, but my impression is that what they want is not so much the presence of the sun, but the absence of cold. In this garden, which overlooks the sea and is swept by east winds, I am growing them—babianas and tritonias—on either side of a paved path running east and west, where they get a good deal of sun, and they are increasing so rapidly that they will have to be lifted and divided next year. In a former, more sheltered garden of mine I grew a most successful row of babianas as an edge to a border under a west wall, where they got no sunshine until after 11 a.m. They multiplied so freely that finally they edged nearly every border in the garden! Of course, except for purposes of division, they were never lifted, but left severely alone. I also raised a good many seedlings as they come up from seed as easily as gladiolus or schyzostilis.

But I sent some bulbs to my old friend, Mr. Sydney Morris of Earlham (of "Montbretia" fame), hoping that in the sandy soil of Norfolk they might flourish, but he said the first Norfolk winter killed them outright. Ixias and sparaxis also do here quite well and I have recently sent to Africa for some bulbs of their gladiolus species, "Painted Ladies," and so forth, to see whether I can do them. They are just starting to come up. The sunshine here is never as hot nor as scorching as it is in England, but we get little snow, and our severest frost [illegible] the past winter was only 4 degrees, and that was only for one night in the most exposed places. I do not think that I had any frost here, but, of course, the wind was very cold and my acacias (mimosas) suffered, although Tacsonia Jamesoni, which every one told me could not stand a winter out of doors, never turned a hair and is now covered with fresh shoots. Your paper has been such a help to me as well as being a perennial joy that I hope this little note of mine may be of some help in return. I have just received a catalogue from California mentioning a Fremontia mexicana, as well as californica, which does well here. Did you know of this orange variety? It is not in any other English or French catalogue in my possession.—EDITH F. CAREY, *Guernsey*.

THE PRUNING OF SHRUBS.

SIR,—In Mr. Grant's note on the above in the issue of THE GARDEN of April 24th I hope Mr. Grant has not misconstrued my note on the same subject on March 27th, page 194, when he quotes me as follows: "Lavatera olbia he cut back every year *previous* to it dying back," what I did write was, "We find shrubs like Malva olbia and shrubby veronicas must be pruned hard to 'save' them dying back."

In these gardens on the east coast of Essex and only four miles from the sea, Malva olbia makes a lovely shrub without any protection, but it had an unpleasant habit of one or two of the large branches dying back and thus spoiling the appearance of the specimen.

After much trouble we overcame this difficulty by pruning hard back. The same thing we find applies to Abutilon vitifolium, which, also, from some unknown reason, dies back a large branch at a time.—R. MOORE, *Thorpe Hall*.

PLANT NOMENCLATURE.

SIR,—Does not Mr. Dalrymple break the rules of plant naming in giving varietal names ("Lady Thursby," "Hew Dalrymple," etc.), to *seedlings selected to colour* from the Bartley strain, in which there are, to quote his own words (THE GARDEN, lxxxix, page 381), "*four or five*"—the italics are mine—"different pink forms. . . . I have never troubled to isolate and grow each one separately and as the bees cross the flowers of the various shades, so the seed from any one form will reproduce all or any of the various shades." As selections to colour from the Bartley strain, they should be named accordingly, *e.g.*, Primula pulverulenta, Bartley strain, rose pink.

Cannot our raisers be induced to restrict the application of names to varieties which are either propagated vegetatively from the original plant, or which breed *true* from seed. Thus, Primula pulverulenta Mrs. R. V. Berkeley, mentioned in the letter quoted above, is a variety entitled to a varietal name.—F.R.H.S.

AMERICAN EXHIBITS AT THE FORTHCOMING AMATEUR SHOW.

SIR,—As your readers are aware, the Royal Horticultural Society decided to invite amateur gardeners in the United States and on the Continent, to compete with British amateurs at the Amateur Show on June 22nd.

I have now heard from Mrs. Edward Harding, that in spite of the severe handicap of transportation, several American amateurs have accepted the invitation to exhibit at the Show, which I conveyed to them at the request of the Council. They regard "trans-Atlantic exhibiting as a compliment to their British cousins and as a sporting proposition." I am sure all gardeners wish them every success.

May I take this opportunity of appealing to British nurserymen and seedsmen to show themselves to be sportsmen and to remove the embargo which they have placed on certain firms on the Continent, who have a retail as well as a wholesale business, exhibiting at shows in Great Britain and Ireland.

The chairman of the Edinburgh International Show last year told me he had invited two Continental firms of world wide reputation to exhibit and both had replied that they were debarred by the opposition of their English wholesale customers.

Continental shows welcome foreign exhibits, and the Royal Horticultural Society is always glad to stage exhibits from overseas, a policy which is indubitably in the best interests of horticulture.—WILLIAM LAWRENCE.

FLORAL ANTIQUITIES.

SIR,—A new method of getting into touch with missing friends and tracing the whereabouts of individuals who have drifted out of sight has lately come into considerable use by means of broadcasting; and it occurs to me to ask you to send out a general enquiry through your far-reaching columns in the hope of discovering one or two old friends whose acquaintance I would like to renew.

Many years ago I had in the garden which was then mine a distinct and favourite viola named Magpie, the flower being rather loosely built, somewhat of the gracilis type, and to describe it as black and white in colour is not far from being accurate. I have sought high and low for it, but if it still survives it must be in some well hidden retreat, for my many and repeated enquiries have so far failed to discover it.

Then, again, I would much like to find one or two old favourites of my younger days among the shrubby calceolarias, for which I have also made fruitless search. Garibaldi, Mount Etna, Goldcap and Victor Emanuel were some of them. They were offered in plant lists published away back in the 'seventies (one of which I have recently seen), but I cannot find them mentioned in any lists to-day. The only hope of finding them again seems to be in a quiet retreat for aged plants in the keeping of some fragrant-hearted lover of floral antiquities who has not altogether cast off old loves for new.

THE GARDEN is an increasingly charming and helpful paper, and I feel inclined to suggest the devotion of a little space—down in one corner and always in the same position—where could be put "Wanted to Find" items such as these about which I write.—W. D.

GARDEN TECHNIQUE

VEGETABLE GARDEN.

SOWING ASPARAGUS FOR NEXT SPRING PLANTING.

THE asparagus is regarded as a very choice, valuable vegetable and it should be grown in every garden. But where the soil is clayey, cold and tenacious, it is a very difficult matter to succeed in growing really fine produce without taking extra pains. To sow the seeds directly in an unprepared bed, or in one not specially prepared is to court failure. The best plan is to make up a special bed for the reception of the seeds and to sow the latter in it forthwith. The border should be raised at least 4ins. above the normal level; the soil must be thoroughly broken up and some leaf-soil and such compost as old potting soil, sifted and mixed with it. Form drills about 2ins. deep and 1ft. apart; sow the seeds 2ins. apart in the drills and nearly fill up the latter with the sifted soil. It will not require a very large bed to contain about five hundred plants and the seeds will soon germinate in it and become very fine specimens by the end of the summer. While the young plants are making progress every effort should be made to form the permanent beds in which they are to be planted next spring. The soil should be deeply dug and the subsoil loosened and broken up as finely as possible. Various crops of vegetables may be grown during the summer and, in the autumn the asparagus beds should be formed but left in a rough state all through the winter in readiness for planting in due course.—CHRISTCHURCH.

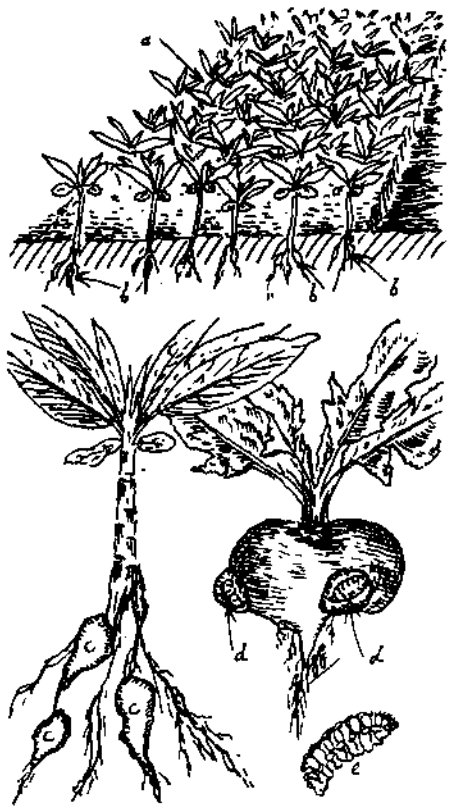
PREPARING HOLES FOR ROOT CROPS.

IT is necessary, if one wants to obtain fair-sized roots of parsnips and salsafy, to have the seeds sown now, so that the plants have sufficient time to grow and develop properly; yet the time of seed sowing is not the only item conducive to good results. In garden soils of a heavy texture root crops of the tap-rooted types grow branched—or, in the language of the garden, the roots are forked. To avoid this, and to get long straight roots, it is necessary not only to have the soil deeply dug, but to make holes anything from 12ins. to 20ins. deep with a strong dibber. These holes should be filled with old potting soil, after it has been passed through a ¼in. sieve and well mixed with a quantity of fresh wood ashes.

At the top of each hole a few seeds should be dropped, and covered with a sprinkling of soil. When the seedlings are sufficiently advanced they should be thinned out to one plant per hole. By this method of preparing the holes—which certainly takes more time than making drills—one can get good straight roots, which are more to be desired than quantities of the others.—DAVID ARMSTRONG.

CLUB IN CABBAGE. GALL-WEEVIL IN TURNIPS.

THE disease and the pest are not confined to the two kinds of plants named above. They are, however, the crops that are often seriously damaged by them. The effects of both are almost similar, but the causes are quite distinct. Dealing with club-root first, it is caused by a slime-fungus which spreads rapidly in a sour soil. The malformed roots, in bad cases, swell to a large size, often split open, decompose and soon become very offensive. Soil deficient in lime is a fruitful medium for the spread of the disease. In small gardens seeds of cabbages, cauliflowers, savoys, Brussels sprouts and winter greens generally are, year after year, sown in the same part of some nice sheltered border, with the result that the young plants are affected before they are planted out in their permanent quarters. I have seen this happen many times, the roots being mere lumps without fibre. Such plants should be burned. Overcrowded seedlings are shown at *a*, with their roots, *b*, *b*, *b*, "clubbing." Fresh soil should be selected in which to raise the seedlings and a change of plot given every year. This applies, too, to the permanent planting out. When a young plant "clubs" in the seed quarters, it soon becomes useless, as shown at *c*, *c*, *c*. The stem swells, sometimes splits, and the tops droop directly the sun shines on them. Gas-lime applied in the autumn at the rate of one bushel per square rod will do a lot of good. It cannot be obtained freely, so in its place use two bushels



of ordinary lime and in spring one peck of salt per square rod. The turnip-gall weevil causes those smooth knobs on the sides and base parts of turnips, and they also affect the roots of cabbages and greens. Gas-lime is beneficial in this case too. It should be left on the surface several weeks before it is dug into the soil. All cabbage and similar plant stumps—and their roots—should be burned, and change of crops is good. Wood-ashes and charred rubbish and soil should be freely added to the garden soil every spring; *d*, *d*, and *e* show the maggots.—GEO. GARNER.

PRICKING OFF CELERY.

THIS is a popular vegetable with most small-holders, but, unfortunately, it is not grown to such perfection in some cases as it might be. One reason for this is through neglecting it in the early stages. The plants are kept too long in a high temperature, or they are pricked off into boxes of poor soil and allowed to become stunted, and as the soil is poor they are also starved. A better plan is as follows: Spread about 3ins. of compost manure on a hard ash bottom, if possible, and upon this put about 2ins. of good loamy soil; pat it down moderately firm.

Some 6in. battens should be placed on the beds in such a manner as to carry a 6ft. light, to be put over the crop. The plants should be pricked off into these beds about 6ins. apart. Careful attention in watering and weeding should be observed, and when the plants commence to grow plenty of ventilation will be necessary.

The lights should be removed altogether as time goes on, and can be used for other purposes. Once celery has made a good start, any kind of shelter will do to protect it from cold winds. When the plants are being removed to the trenches they can be cut down to the bottom of the beds in squares, and those who adopt this method will find it a good way of preparing celery plants, as the plants do not by this method receive any check at planting time, and thus the stems grow nice and tender thereby. Celery that is checked in growing frequently grows pithy and poor and has a tendency to run to seed. The plants should be dusted at regular intervals with soot to prevent the fly from depositing its eggs in the foliage, where the larvæ play havoc by mining in the leaf.—G. BARTON.

FLOWER GARDEN

SWEET PEA NOTES.

AT this time of the year, our sweet peas—whether autumn or spring sown—should be well established in their flowering quarters. It must not be expected that they will make real headway for a week or two after transplanting, often they appear to be perfectly stationary until their roots begin to move freely. Inexperienced growers are tempted to give frequent waterings or even to apply some form of stimulant, but rarely do they need either watering or feeding from the time they are transplanted until they commence to bloom. Feeding, indeed, is unnecessary and may prove very harmful before they flower. Keep the hoe going round the plants to conserve moisture and as soon as the first flower buds appear, give a top dressing or mulch of loose horse litter or spent hops.

During the period between transplanting and the time they commence to make rapid growth, slugs are often a source of trouble and disappointment, and unless steps are taken to prevent their unwelcome attentions, serious losses—sometimes irreplaceable—are incurred. Of course, the best time to check slugs is in the late summer and autumn of the previous year. This may sound "Irish," but in a wet autumn, they multiply with extraordinary rapidity among weeds, refuse and in thickly planted borders. Keep the garden clean and free from weeds and rubbish during this period and slugs will give little bother the following spring. If only a small number of sweet peas is being grown, dusting lime or soot (not both) or finely sifted ashes, each side of the rows or all round the clumps is fairly effective, for slugs and snails do not like crossing these substances if they are dry. Apart from the lengthy method of examining the plants in the late evening or early morning in damp weather, picking off and killing all slugs one can find, another way is to lay cabbage or lettuce leaves along the rows in the evening and turn them over the next morning, destroying any slugs which may have solved the housing problem by crawling underneath for both shelter and a square meal. Potato slices and little heaps of bran also make good slug traps. Several preparations are on the market which will kill slugs if sprinkled on them (in powder or liquid form), but I have, as yet, found nothing which will destroy

Digitized by Google

slugs underneath lumps of soil and stones without injuring the plants.

In the country, where other greenstuff is plentiful, birds give little trouble, but in suburban districts, they sometimes nip out the tender and juicy growing tips. Autumn sown plants will by now be too large to attract them, but later sowings may be protected with a few strands of black cotton or twine stretched just above the plants.—C. H. A, S.

NOTES ON LUPINS.

LUPINS are easily grown and can stand a good deal of ill usage—if one might be allowed to use that phrase—at any rate I have seen fairly large plants transplanted—about the middle of May—when growth was well advanced. Certainly they did not attain to the height of established plants, but in regard to length of flower spikes, there did not seem to be any marked difference. It was observed, however, that a greater number of flowers had dropped from the spikes of the undisturbed plants, than from the plants transferred in May. It should be mentioned that these remarks on flowers dropping relate only to the white-flowered variety—Lupinus polyphyllus albus. It certainly detracts from the perfectness of the spikes, when they are bare of blooms for almost half their length, as often occurs.

Perennial lupins luxuriate in a fairly heavy soil, and one in which well rotted manure has been freely incorporated. Timely staking and tying are necessary so that the easily displaced growths and flower stems will not be broken down when high winds prevail. The old stems, too, should be cut over as soon as the flowers are past, as lupins set freely and produce large quantities of seed, which, if left to mature, will weaken the plants. The appearance of the plants is also improved when the old flower stems are removed early.—DAVID ARMSTRONG.

A FINE WINTER-FLOWERING BEGONIA.

WINTER-FLOWERING begonias have never become popular among amateurs, but there is one variety which ought to suit them better than any of the others, Begonia Ideala. This particular kind is of compact habit; it grows into a neat plant without any particular care on the part of the grower, and it seldom shows that "legginess" which is characteristic of similar plants badly grown.

This is the correct time to procure cuttings and to strike them for next winter, although cuttings may be struck at any time. A brisk bottom heat is required to propagate, and a fairly high temperature, round about 65° Fahr., is needed for their general culture. Grown on in a loamy compost enriched with some well decayed cow-manure and kept in a moist atmosphere, this variety will grow rapidly and soon make good specimen plants. Flower the plants in 6in. or 7in. pots. The flowers are of the usual Lorraine rosy red colour, of fair size, and borne in great profusion.—H. A.

THE GREENHOUSE

SWAINSONIAS.

IT is somewhat remarkable that Swainsonias are grown so rarely in greenhouses to-day, considering their comparative easy culture, their adaptability for climbing over rafters or inside walls, and to the multitudes of sprays of pea-like blossoms they yield. They are evergreen climbing plants, that once established give very little trouble, beyond occasional shortening of the shoots; may be raised either from seeds or cuttings in spring and can be finally potted in large pots, or planted in a border within the house as occasion and convenience serve. In sowing seed, a compost should be made up of fibrous loam and peat, with a good proportion of silver sand. Young plants should have their shoots pinched once or twice to admit of lateral growths, and frequent syringings, accompanied with moisture at the roots will do much towards keeping swainsonias healthy and vigorous during the summer season. Shade is essential to their well being. They will thrive in a temperature of 60 degrees (winter minimum 45 degrees, when they need to be kept on the dry side). It will be found the better plan to encourage growth the first twelve months, rather than flower buds to form. This will be appreciated in the second year when shoots are laden with flowering sprays. S. galegifolia, rose, and S. galegifolia alba, white, are both attractive. The growths are slender and twining, being amenable to training under the rafters of a shaded roof. It is to be feared, however, that, so far as the average greenhouse is concerned, swainsonias are a vanishing race.—W. F.

REPOTTING AND STOPPING TREE CARNATIONS.

CUTTINGS of these may be rooted any time during the whole year, and so repotting is work that requires attention from time to time. But the two principal stocks of plants are raised from cuttings inserted in October and in the New Year until as late as March. The first, or autumn-struck, stock supplies flowering shrubs by the early part of the following autumn, often they begin to bloom in the late summer-time; and the spring-struck plants yield blooms profusely early in the New Year. The February and March rooted cuttings should be potted singly as soon as possible, or the stems will be drawn up weakly. If kept in a greenhouse it should be only for a short time, then transferred to a cold frame, and be shifted to larger pots directly the small ones begin to fill with roots. When established in the second-sized pots, stop the plants at five or six main leaves from their base. It is chiefly owing to non-stopping until the stems are 8ins. or 9ins. high and then only removing the tips that lanky, ungainly specimens result. The side shoots should grow freely from the lowest joints—axils of leaves and stem. The earliest plants, judiciously stopped, will now possess many side shoots, approximately 6ins. long. Some of these may be stopped again. The plants should be finally potted as soon as possible. Use old mortar rubble, pounded bricks and some bone-meal in the compost. Pot firmly.—GEO. GARNER.

MISCELLANEOUS

CONTROL OF WINTER MOTH.

THERE is very real evidence that the larvæ of the winter moth (Cheimatobia brumata) will be very destructive upon bush fruit trees this season, unless they receive an effective check. As usual, apples will be the worst sufferers, but pear, plum and cherry trees carry a complement of the pest as well. No remedial measures can be applied while the trees are in bloom, but they should not be delayed one moment longer than is necessary after the flowers have fallen. I know of none but an arsenical specific which carries a principle that is fatal to the larvæ of the winter moth. It is unfortunate, perhaps, in view of the arsenic scare, but there is, of course, no possibility of permanent effect when spraying is done so early. The trees should not be sprayed with an arsenical wash if vegetables are growing beneath them. I have proved time and time again that arsenate of lead makes an effective base for the destruction of winter moth larvæ, when dissolved in water at the rate of half a pound to twelve gallons. In common with many larvæ destroyers this one poisons the food. It must, therefore, be applied to the trees in the form of a mist-like spray. A dry, dull and calm day is ideal for the purpose. In no instance should the trees be sprayed in a fresh wind, or the operation cannot prove effective. Readers who have not an intimate knowledge of entomology may welcome a description of the larvæ of the winter moth. In infancy they have greenish yellow bodies and brown heads. At maturity they are yellow and measure three-quarters of an inch in length. They are known as "measurers" in many parts of the country, because they progress in a manner similar to that of a hand spanning the distance between two points. Possessed by a voracious appetite the larvæ feed upon the leaves and blossom, reducing or entirely destroying the prospects of a remunerative fruit crop.—GEO. H. COPLEY.

DAMPING OFF.

SEEDLINGS and greenhouse plants are particularly subject to "damping off." That the chief cause of this is over-watering is well known, but it is also caused by lack of sunshine and excess of moisture in the air. So one way to avoid it in greenhouses and frames is to allow plenty of ventilation in all but the most frosty weather.

If the "damping" process has gone far it is almost hopeless to try to cure it, but if caught in time plants may be saved by dusting sulphur lightly over the affected parts, though care must be taken not to leave sufficient on to choke the stomata or breathing pores of the leaves. It is sometimes sufficient to sprinkle the sulphur on the floor and staging of the greenhouse, though if it is left on pipes that are too hot the fumes will be injurious to the plants.

As prevention is always better than cure, it is well to attend to the following points regularly, as this will go far to avoid the trouble. Both over-watering and over-feeding must be avoided, especially in cold weather, when plants cannot make use of so much manure, and it may sour the soil by standing it in too long. All plants, but especially seedlings, will greatly benefit by having the surface soil broken up frequently, as this will keep it sweet and prevent greenness on top.

Go over your plants regularly, and prick off all parts that show signs of decay, as these will mildew rapidly and spread infection, if small scissors are used, single blooms can be removed from trusses without spoiling the whole.—MICHAEL J. DEARDEN, *Swansea*.

IMPROVING MINT.

A BED of mint will last indefinitely, but after a few years it will be improved by a good overhauling, and may even need removing to a new site. This may be due to mint rust having set in, for which there is no real cure; but it is more likely to be due to such weeds as bindweed and couch grass having established themselves among the mint, and as their underground stems closely resemble those of the mint, it is almost impossible to get rid of the one without destroying the other.

If the bed is free from both rust and weeds, it will benefit by having the top cleared off, the surface soil loosened, and a good layer of leaf-mould spread over it.

When choosing the site for a new bed it is well to have it facing south or west, so that early mint can be obtained without forcing. Very deep digging is not necessary, and as the wild mint is found chiefly in the rich soil of river banks it is obvious that plenty of well rotted manure will improve the crop if added while the bed is being prepared.

The mint should be planted in rows about 10ins. apart, and 2ins. or 3ins. deep, and the roots spread well out. The most common mint is Mentha piperita, but if new plants are bought it will be found more satisfactory to obtain, if possible, the M. virides, or spear mint.—M. D.

OBITUARY

MR. SAMUEL McGREDY, J.P.

IT is with the deepest regret that we have to announce the death of Mr. S. McGredy, who passed away at his home at Portadown on Monday, April 26th, at the age of sixty-five. He had been in failing health for some time past, suffering from heart trouble.

Without doubt he was a wizard of the rose world and will be greatly missed by all lovers of our national flower. One can safely say that no single person has done more to beautify our rose gardens than the late Mr. McGredy, and it would be a fitting memorial if the N.R.S. struck a special medal to be offered at their summer shows and so keep his memory green among us.

He lived and died for the rose, and was always ready to help and give valuable advice to all those interested. The writer has known him since about 1905, when he first became known to the rose world. At all times, when visiting him at Portadown, one was always sure of a hearty reception, and to wander with him through his nursery was a real pleasure.

May the great work which he started and so loved be continued successfully by the house of McGredy. Before taking up the hybridising of roses, which he did as a hobby, I believe one is quite right in saying that he was a great lover of horses, and if my memory serves me well, he bred many well known hackneys which he used to exhibit with a good deal of success at the leading shows.

Readers will probably remember that last year's volume of THE GARDEN was dedicated to Mr. McGredy for his great and untiring work in the rose world.

MR. ISAAC McDOUGALL.

IT is with deep regret that we have to record the death of Mr. Isaac McDougall, which took place in London three weeks ago.

Mr. McDougall was formerly chairman of McDougall and Robertson, Limited, Manchester, and also of McDougall and Yalding, Limited, and subsequently became vice-chairman of Cooper, McDougall and Robertson, Limited, upon the amalgamation of these companies with Wm. Cooper and Nephews, Limited, of Berkhamsted.

Throughout his life Mr. McDougall was closely associated with horticultural interests, his companies being manufacturers of a wide range of insecticide sprays, etc., used by fruit growers, gardeners and horticulturists both in this country and abroad.

After leaving school he went to the Swanley Horticultural School, at that time a men's college, and was afterwards pupil at the farm of Mr. (now Sir Walter) Berry at Faversham.

When only nineteen years of age he started farming on his own account at Red Hill, Wateringbury, but after a few years joined his father in business at Manchester, and subsequently became chairman and managing director of McDougall Brothers, Limited, of that city.

A keen and capable business man he combined a genial and generous nature with an unbounded capacity for hard work and successful organisation. He was a model employer and enjoyed, not only the respect and esteem, but in an unusual degree the personal affection of his staff and employees.

His death at the comparatively early age of fifty-three, will be deeply regretted, not only by his family and business associates, but by an exceptionally large circle of friends in all parts of the world.

CISTUS HILLIER'S SILVER PINK

Award of Merit, R.H.S., June 17, 1919.

Flowers the most charming art shade of pale silvery pink, large and profusely borne. Foliage silvery grey; very hardy. **2/6** each. **27/-** doz.

COLLECTIONS OF

(*a*) **12** Cistus in **12** leading varieties, all shades of colour, including purpureus, Loretii, algarvensis, etc., for .. **21/-**
(*b*) **12** ditto, in second size plants, for **16/6**
(*c*) **6** Cistus, in **6** older varieties, for **7/6**

All the above are bushy plants in 5-inch pots.

HILLIER & SONS of WINCHESTER

DOUBLE PRIMROSES

DOUBLE primroses are not always easy plants, but with a fuller realisation of their wants there are few who need despair of growing them to perfection. The fact that they do best in the north and west, where the rainfall is greater, bears its own significance. They dislike dry, poor soils and cutting winds. They want a deep, rather rich, cool soil of medium texture but freely drained, and a little shade from the hottest sun is advisable. An occasional breaking-up and replanting in a fresh bed does much to maintain that natural vigour which in plants that have for generations been propagated only by division is apt to deteriorate. It is not less important to see that a free and healthy development of foliage takes place during early summer, and this, in some places, may mean a few good drenchings with water, followed in the case of the less robust (usually the darkest coloured forms) by some weak liquid manure.

The late spring, just when the flowers are over, is the best time for planting double primroses, as it is the most favourable for that lifting and division of old clumps to which I have referred. No difficulty attends these matters. If the weather be dry, the plants should be well watered for a few weeks, and a little shelter from the midday sun may be desirable. As a rule, these primroses are most pleasing when disposed in informal groups, due attention being paid to the associating of the colours; but a natural aversion to dotting never need mar the delight of having a single plant placed here and there in the mixed border.

Varieties in double primroses are many, the colour range being extensive, and there are notable differences in the size and form of the blossoms. To all these individually one need not refer, but among the best in colour and bloom formation are the lilac, yellow, white and velvety crimson Mme. Pompadour. Other good sorts include a deep purple, rosy lilac, crimson splashed with white, purple laced with silver or gold, a sulphur yellow, dark and light violets, crimson scarlet and amaranthe. Within the last few years one or two double blues have appeared, but I have not yet seen one of them equal to the best single blues in colour. Corymbose or

ANTIRRHINUMS

IT'S only the fact that we grow and deliver especially good plants that we wish to advertise. The brightness, the long-flowering life, the wonderful adaptability of Antirrhinums (Snapdragons) are known to everyone. Although our plants are properly grown, transplanted, well rooted, hardened off, in all ways particularly good, as becomes a firm which reckon to do things well, the price is only

1/3 dozen. **8/6** 100.

Carriage paid on orders value 5/- and over, otherwise 9d. extra.

And these are the varieties and colours

Codsall Rose, delicate pink
Cottage Maid, pink, white throat
Crimson King, rich dark crimson
Dainty, gold and terra cotta pink
Electra, salmon orange, white throat
Dazzler, orange scarlet
Firefly, scarlet
Glow, orange apricot
Melrose, bright rose
Rose Queen, rose pink self
White Queen, pure white
Yellow King, rich yellow

CORRY & CO, Ltd., Shad Thames, London, S.E.1

FERTILISE FREELY!

Fertilise freely or all your labours in the garden will be wasted. Plants must have Nitrogen, and the best form is Nitrate of Soda in conjunction with phosphates and potash.

Write for pamphlets, entitled, "Successful Gardens for Every Amateur," "The Manuring of Orchards and Fruit Trees," supplied gratis and post free by THE CHILEAN NITRATE COMMITTEE, Friars House, New Broad Street, London, E.C. 2.

RICHARD SANKEY & SON, LTD.,
Royal Potteries,
BULWELL, NOTTINGHAM

polyanthus heads, which sometimes occur in the double primrose, must not be taken as an indication of impurity of strain. Such often arise, especially towards the end of the flowering season, which, with most kinds, extends from February to about the end of April.—A. T. JOHNSON.

TRADE NOTES.

THERE are some native plants which, provided with suitable conditions, may be naturalised in the wild garden or the woodland. These wild flowers are perfectly hardy, they bloom year after year without any attention, and possess a charm and beauty of their own. The Native Plant Nurseries, Rochbeare, near Exeter, Devon, specialise in wild flowers and ferns of all kinds. This firm supply at very reasonable prices, wild plants suitable for woodland, wall or rock garden, bog garden and woodland.

ONE of the most striking and richest toned of the brooms is the new hardy crimson variety known as Dorothy Walpole. This broom created quite a sensation at Chelsea Show last year. It is perfectly hardy, very free flowering, with wings of a most attractive rich crimson and standards of rosy red. It succeeds equally well in the north as in the south, and from the colour point of view alone this fine broom is worthy of a place in every garden.

PUBLICATIONS RECEIVED.

"Everyman's Book of Garden Flowers," by John Halsam (Hodder and Stoughton, price 6s. net). This is a new and revised edition of this excellent publication, in which so much practical and valuable advice is packed in such a concise and compact form. The illustrations alone, of which there are a hundred and twenty-eight, are worthy of the attention of every gardener, while the cultural directions given in every case of some two hundred and fifty border flowers are well worth following. It is a little book which all those who garden in a small way should have at their hand.

"Gardens for Town and Suburb," by V. N. Solly (Ernest Benn, Limited, London, price 15s. net).

CATALOGUES RECEIVED.

Where space permits, one of the most useful adjuncts to any garden is a garden frame or small greenhouse. More interest and pleasure can be taken in one's gardening by raising one's own seedlings and carrying out in a small way the propagation of some of the inmates of the garden. Certainly much more can be learned about the intricacies of a plant through the possession of a little glass, and it is in this connection that we would draw attention to the lists of Messrs. David Swain and Co., Horticultural Builders, Sussex Road, Holloway, N.7. The various types of greenhouses and garden frames are described and illustrated and the keen amateur gardener would be well advised to look them over. He is sure to find something to his liking and in keeping with his purse.

Two interesting daffodil lists have also come to hand. These are from Messrs. Donard Nursery Co., whose list offers a wide selection of new and choice narcissi, and Messrs. Cartwright and Goodwin, which is equally wide in its range. Many of the fine varieties shown by these two firms at the recent Daffodil Show will be found in these two lists and we advise all daffodil lovers to procure and study them before the bulb order comes round for 1927.

Messrs. Jeans and Trowbridge, Alpine Nursery, West Moors, Dorset.—A select list of alpine and rock plants.

Mr. C. E. West, Higham Hill, London, E.17.—List of horticultural sundries.

By Appointment.

"SANITAS" POWDER

SAN 247-62

Do you take the trouble to grow vegetables, plants and flowers, just for the insects to enjoy? You can be sure of better results in your garden if you keep a tin of Sanitas handy. Sprinkle a little powder in the drills when you sow, and round the tender shoots; it keeps off all insects and pests; does no harm to the plants.

WAKELEY'S Celebrated Hop Manure

(PATENTED)

THE ORIGINAL AND ONLY RELIABLE SUBSTITUTE FOR STABLE MANURE

AS USED IN THE GARDENS OF GREAT BRITAIN

DIPLOMA AND MEDAL, ROYAL INTERNATIONAL HORTICULTURAL EXHIBITION, 1912

DO YOU REALISE IT?

A large bag of WAKELEY'S PATENTED HOP MANURE at a cost of only 7/- carriage paid to your door (if within 25 miles radius of London, or at a trifling extra if beyond), GOES AS FAR AS A CART-LOAD OF STABLE MANURE, without any of the defects of the latter; gives better results, is easy and clean to use.

Every ounce of Wakeley's Hop Manure is of value to the soil, supplying the necessary HUMUS in addition to the valuable plant food. Worthless rubbish is not added to make weight (as is the case of some artificial manures advertised).

Thousands do realise it, the proof of this is the constant flow of UNSOLICITED LETTERS received from time to time in praise of the wonderful results obtained at such a moderate cost (see Booklet for selection).

We are exhibiting at the ROYAL CHELSEA SHOW, kindly visit us at STAND No. 103, SUNDRIES AVENUE.

BEWARE OF IMITATIONS.—Genuine Only in our Marked Bags containing Guaranteed Analysis.

ILLUSTRATED CATALOGUE giving full particulars and testimonials sent on receipt of post card.

CASH PRICES (including bags):

Small (about 1 bushel)	3/-
Large (about 4 bushels)	7/-
5 Large	33/9
10 Large	65/-
20 Large	120/-

Carriage paid by Pickford's or to any station within 25 miles of London, including delivery if within free delivery radius of Railway Company; 6d. per bag extra for every 50 miles or part beyond. Maximum extra charge Great Britain, 2/6 per bag.

NEW AND RARE NARCISSI

SPECIAL EARLY OFFER for the sake of Colonial Visitors and those who like to order early

F.C.C., R.H.S., signifies First-Class Certificate, Royal Horticultural Society. A.M.—Award of Merit. The date after raiser's name indicates the year the Daffodil was put into commerce. The Letters and Figures placed before each variety denote its position according to the Classification of the R.H.S.

BARBARIC (Chapman, 1925). A very fine showy flower after the style of Brilliancy, but much larger. Long pointed perianth segments, cup orange. A long stemmed and vigorous plant. Mid season. **£2 2s. per bulb**

1b **BEERSHEBA** (Engleheart). This is a real advance in white trumpets and is built on somewhat new lines. Trumpet long and slightly funnel-shaped; segments long and slightly pointed. Stalk longer than most of the pure white Daffodils. A very distinct and beautiful show flower; growth vigorous and free. F.C.C., R.H.S., 1926. **£8 per bulb**

1c **CARMEL** (Brodie of Brodie). Perianth absolutely smooth and flat, the pure white segments overlapping with perfect evenness. The trumpet is of beautiful form, with a neatly recurved brim: colour clear yellow. A superb flower of perfect balance and show form. Good healthy grower. A.M., R.H.S., April, 1926. **£4 per bulb**

3 **FIONA MACLEOD** (Pearson, 1926). We think this is the largest and best formed Poet we have yet seen. The segments are very rounded, and of very firm texture. The whole flower measures 3¾ in. across. Stalk 18 to 20 in. long. Late. **25/- per bulb**

1a **GENERAL TOWNSHEND** (Pearson, 1924). This may best be described as a much improved Lord Roberts. A large firm flower of show quality, borne on long stalk. Plant vigorous and free, with broad foliage. Mid season. **10/6 per bulb**

4a **GERTIE MILLAR.** A giant among the Giant Leedsii. When fully expanded the whole flower is ivory white. It is a real giant, the whole flower being 6 inches across, while the frilled cup is 3 inches across. A sensational flower. **£3 per bulb**

4a **HYMETTUS** (Brodie of Brodie). A most distinct and charming flower, spreading pure white perianth of large diameter; the cup is not so long as in most Giant Leedsii, and is most attractively reflexed and frilled at the brim. When fully developed it is ivory white, margined with clear lemon. **15/- per bulb**

1c **LADY MINE** (Pearson, 1923). A very bright clear bicolor trumpet Daffodil. The flower is of good form, substance and pose, and is carried on long stalk. The habit of plant is quite remarkably vigorous and free. **15/- doz. 1/6 each**

2a **LUCINIUS.** A very fine Giant Incomp. of Dutch origin. Whole flower bright clear yellow. The perianth is of faultless form: the cup is large and rather spreading. Long stalk and good healthy habit of growth. Rather late. **12/6 per bulb**

4a] **MITYLENE** (Engleheart, 1925). A new break in this section. A grand flower, having very broad and rounded, very much overlapping segments of pure white, large wide and smooth saucer-shaped cup, of pale primrose, fading to cream. A superb show flower. A.M., Mid. Daff. Society, April 23/25. **25/- per bulb**

1c **MOIRA O'NEILL** (Engleheart). The most refined and beautiful bicolor trumpet yet offered. The large flower is perfect in shape and pose, and the plant is extremely vigorous, having leaves broader than Emperor. **30/- per bulb**

4a **MRS. R. O. BACKHOUSE** (Late Mrs. R. O. Backhouse). A quite unique flower. A Giant Leedsii of trumpet proportions. The perianth is white; the trumpet is creamy white, edged and shaded with a most distinct tinge of pink. Originally sold at £50 per bulb. **Now offered at £15**

3b **PRINCESS MIRIAM** (De Graaf, 1924). A large and beautiful flower; perianth white, flat, and perfectly formed. The cup is yellow edged orange. Very long stalk, plant vigorous and free. Very late. A really good novelty at a moderate price. **25/- per bulb**

1c **ROSARY** (Engleheart). This variety has undoubtedly Leedsii blood in it, but by measurement it goes into the bicolor trumpet section. The flower is of largest size, and of fine substance, having large white perianth, and splendid big well-expanded trumpet, rich warm cream colour, distinctly suffused with a flush of shell pink. The colour only develops on the plant; if cut in bud it does not develop. Strong plant with broad foliage, rather late. **37/6 each**

3 **STRIKING.** A very fine Poet. Flower firm and well rounded, with brilliant all-red eye. **30/- per bulb**

TENEDOS (Engleheart). Without doubt the finest Giant Leedsii yet produced. Flowers of largest size, borne on very long stalks, plant very vigorous and a quick increaser. Segments pure white, of great substance, slightly pointed. The large cup is pale lemon on opening, passing to white when fully developed. A.M., Mid. Daff. Soc., 1923. F.C.C., Mid. Daff. Soc., 1924. **£4 10s. per bulb**

1c **VESTAN** (Copeland, 1923). A huge bicolor trumpet Daffodil, but not at all coarse. Very vigorous and free. Attracted attention on our stand at Birmingham, April 19th, 1923. **3/6 per bulb**

2a **WHEEL OF FORTUNE** (Copeland, 1923). A very fine Giant Incomp. Whole flower soft luminous yellow; cup large, segments broad, well-rounded and overlapping. Plant strong and vigorous. Voted to be the best flower in the show at Mid. Daff. Exhibition, 1925. **£2 per bulb**

2b **ZILLA** (Mrs. R.O. Backhouse, 1923). A very fine new variety, flower large, segments broad and imbricated, creamy white. Cup large and rather spreading, yellow deeply edged bright orange-scarlet. A good strong grower. Much admired on our Show Stands at R.H.S. and Birmingham, 1923. **30/- per bulb**

DELPHINIUMS

"We lead, follow who can."

The famous ***SOLIHULL INTRODUCTIONS*** *are undoubtedly the* ***elite of the Delphinium World,*** *and the fact that they are* ***Second to None*** *is emphasised by their* ***world-wide popularity.***

The following represent the **finest** obtainable to-day.

COQUETTE. Stately spike of violet shaded mauve. Grand and imposing. **5/-** each

JOY BELLS A lovely delphinium with unique bell-shaped pips of a rich rosy mauve. Distinctive and refined. **15/-** each

MONARCH OF WALES. The giant of them all! Huge massive spikes of fine tapering habit, 4ft. of which is bloom. Guard petals rich blue, with inner ones of reddish mauve. **8/6** each

THE BISHOP. A really refined royal purple with distinct large white eye. A glorious shade and a general favourite. Long spikes of tapering habit; wiry and strong. **25/-** each

VIOLET QUEEN. A very rich blending of violet and mauve. Strong spikes of perfect habit. **10/6** each

WEMBLEY An improvement on the popular "Millicent Blackmore" which it resembles in colour, but its spikes are much larger and more imposing. **25/-** each

VOL. XC.—No. 2843. MAY 29, 1926

ON BUYING AT CHELSEA

CHELSEA is, perhaps, the greatest collection of flowers in bloom that is seen in any part of the world. Many of those who throng the tents go only to look and not to buy, whether they have a garden or not. It is true that this is not the season at which gardeners wish to be bothered with the plant or seed order for next year. It is the time of flower and fruition; and, in any case, few of the plants or seeds can be delivered for many months to come. Still, there are certain advantages in giving definite orders at Chelsea, or, indeed, at any other show. For one thing, the prospective buyer sees so much that comparisons are possible between varieties and types of plants that in many cases cannot be seen so close together on any other occasion. Another point is that memories are short and no catalogue description, however well worded, can ever give an adequate idea of what a plant looks like. All that a catalogue can do is to jog the memory. That being the case, it is much better, if not to give a definite order, at least to take full notes, a simple operation which, by the way, I seldom see being done at Chelsea.

Some may say that there is too much to see and so the powers of human discrimination are blurred. That is certainly the case if the Show is hurriedly seen. I think that most people will agree that the best method is to walk round as quickly as the crowd will allow in order to gain a general impression, and then to return and examine your particular favourites more leisurely. People's tastes vary, which is just as well, so the nurseryman and seedsman has to cater for every conceivable fancy. We try in reporting shows to allow for variation in taste as much as possible; this is particularly the case in our Chelsea Number, for, although this Show is the Mecca of all gardeners, we realise that for every one who visits Chelsea there are ten who would like to but cannot. Probably this will be more true this year than previously, what with difficulties of transport, Whitsuntide holidays and so on. We hope that the Chelsea report will bring home to them some idea of this Chelsea Show and that the report will be varied enough to be useful to all. For them also I suggest that the plan of noting plants specially mentioned is a good one. It is obvious that only a small proportion will be mentioned, but they will be pre-eminent and will stand out above their neighbours in the eyes of the Editorial staff.

Lastly, and by no means least, if you order at Chelsea, you are sure of getting your plants later on. Nurserymen can gauge the demand for a particular plant fairly closely from the orders received at Chelsea; sometimes they may make an error and underestimate. It is better to order now than risk being told later on that the stock of a plant is sold out.

It is in this way that the question of supply and demand, that is sometimes acute in the gardening world, can be mutually arranged to everyone's satisfaction. It is as well to remember that Chelsea is a place at which to buy as well as to look.

E. H. M. C.

"The Garden" Sweet Pea Competition commences in our issue of June 5th.

£50 IN PRIZES

¶ So successful was our rose competition of 1924 that we are about to hold a competition on similar lines, in order that the gardening world may judge for itself which are the six most popular sweet peas.

¶ This competition is decided by the readers themselves, and the number of votes given to each variety determines its final position on the merit list.

¶ The first prize will be goods to the value of £30 from any advertiser in THE GARDEN. The second and third prizes will be goods to the value of £10 and £5 respectively from any advertiser in THE GARDEN. There will be twenty consolation prizes to the value of 5s. each.

¶ All that the competitor has to do is to write what are, in his opinion, the six most popular sweet peas on the coupon which will be printed in the six following issues of THE GARDEN.

¶ For further details regarding this great competition see the next issue of THE GARDEN.

AMATEUR SHOW.

Readers should keep in mind that the Amateur Show of the Royal Horticultural Society is being held as usual at Vincent Square on June 22. It was such a success last year that all amateurs should again show that they can hold their own in the cultivation of plants. Anybody who considers that he has anything out of the common either in the way of cultivation or of rarity should lose no time in writing to the secretary of the R.H.S. for a schedule of the classes. Entries close after the first post on Tuesday morning, June 15th.

WORTHY PLANTS.—I.

IT is to be hoped that a series of notes on worthy plants may be of use to readers, both amateur and professional, of THE GARDEN. These plants will not only consist of new introductions and modern varieties, but also of old favourites that may have fallen into neglect. The only essential is that either the plant itself or a particular use of it is not so well known as it might be. In all cases the plants will be worthy of a far more extensive cultivation. They will also be obtainable in commerce. This is an earnest endeavour to introduce valuable plants to readers who may not have the time nor opportunity to visit as many gardens or see as many flower shows as they would like. Thalictrum dipterocarpum is a case in point. This is a plant that is strangely neglected, perhaps because it has been classed by some writers as being on the tender side. In this they are in error. Here is a meadow rue, stout and sturdy and often six feet in height, that yet keeps its elfin grace. There are few plants of its size that produce flowers of such charm; for they hang like lilac drops of dew from every branchlet. A few amateurs specialise in it and it is often seen at flower shows, yet it has somehow missed the highway to popularity. It is not a difficult plant to grow so long as it can be given a rich loam and sufficient drainage. It is suitable for many a border that is not too dry and not too hot, but its real joy is in semi-shade by the waterside.

THE majority of gardeners will agree that one of the most troublesome pests which can be found within the four walls of a garden is the innocent-looking but avaricious slug. There are few plants which do not succumb to its attacks, which are carried on with a persistence which is surprising for so small a creature. No matter in what part of the garden the plant grows, all are equally susceptible, and in many gardens throughout the country it is little short of wonderful how any plants grow at all. Various methods of trapping and killing them have been suggested from time to time in the columns of THE GARDEN and, although the respective methods have each something to recommend them and meet with a certain amount of success, yet there is often a loophole for escape. It may be interesting, therefore, to those who are ever on the look-out for something novel to try the following plan, contained in a letter which we quote from one of our readers, Mr. John H. Kittow, who writes as follows:

> When I read in your columns of slugs scaling perforated zinc walls to enjoy seedlings of Lilium rubellum and when the same undaunted pest has been found by Mr. Clarence Elliott to make a jaunt of four miles in order to make Campanula Zoysii an *hors d'œuvre* to a meal consisting largely of delphiniums and lupins, then I feel constrained to tell you of my very simple and efficient contrivance to out-manœuvre these gentry.
>
> The susceptibility of both the slug and the snail to electricity is very little realised, but it may be demonstrated by placing in the path of a crawling slug two tiny piece of dissimilar metals. When the wet body of the slug comes in contact with these metals his horns are withdrawn in a flash and he takes another route, having felt the shock of what amounts to a galvanic cell. I therefore surround my valuable plants with two concentric strips of metal—one of copper and the other of zinc—result, Campanula Allionii flourishing and Delphinium Millicent Blackmore well on the way to making her spikes perfect.

We commend the method to any of our readers, as it seems to offer a fair measure of success in the protection of plants from one of the most harmful of garden pests.

IN view of the great success which has attended the usual winter exhibitions of British applied arts and handicrafts at the Royal Horticultural Hall, Westminster, we are pleased to see that the organisers have secured the use of the hall from June 5th to June 11th, to hold a summer display, when the arts and crafts of the garden will be made a noticeable feature. Garden planning and garden architecture receive much attention to-day from the designer and artist, and there are many closely allied branches, such as colour schemes and arrangements, garden ornaments and furniture, and even the clipping of trees and shrubs, which call for the knowledge and service of the specialist in this all-important branch of gardening. It is intended that demonstrations will be held in these subjects in the garden section of the exhibition. In addition, this summer exhibition will undoubtedly pave the way for future developments in the production of those articles related to this side of gardening, and will lead generally to a higher standard being reached by those trade firms who specialise in the manufacture of such goods and we hope, as a result, to increased business. The exhibition will contain much that is of interest to all enthusiastic gardeners, who should not fail to pay a visit to see the more modern side of our almost lost mediæval crafts.

BY the kind permission of the Hon. Vicary Gibbs the gardens at Aldenham House will be open to the public during the Saturday afternoons of July, August and September (excepting Saturday, July 17th, when the Elstree Floral Fête will be held and admission on this occasion will only be by payment), and August Bank Holiday. The conditions will be those ruling in previous years, *viz.*, that no dogs will be admitted, and that children must be under the charge of an adult. It is to be hoped that all of our readers who can, will take advantage of this opportunity to visit these gardens, wherein is housed one of the finest private collections of flowers and vegetables in this country.

AMONG THE ARTICLES IN OUR NEXT ISSUE WILL BE:

EARLY-FLOWERING CHRYSANTHEMUMS, by Norman Lambert.

PRIMULAS FROM TIBET, by Captain F. Kingdon Ward.

Digitized by Google

KEW IN EARLY SUMMER

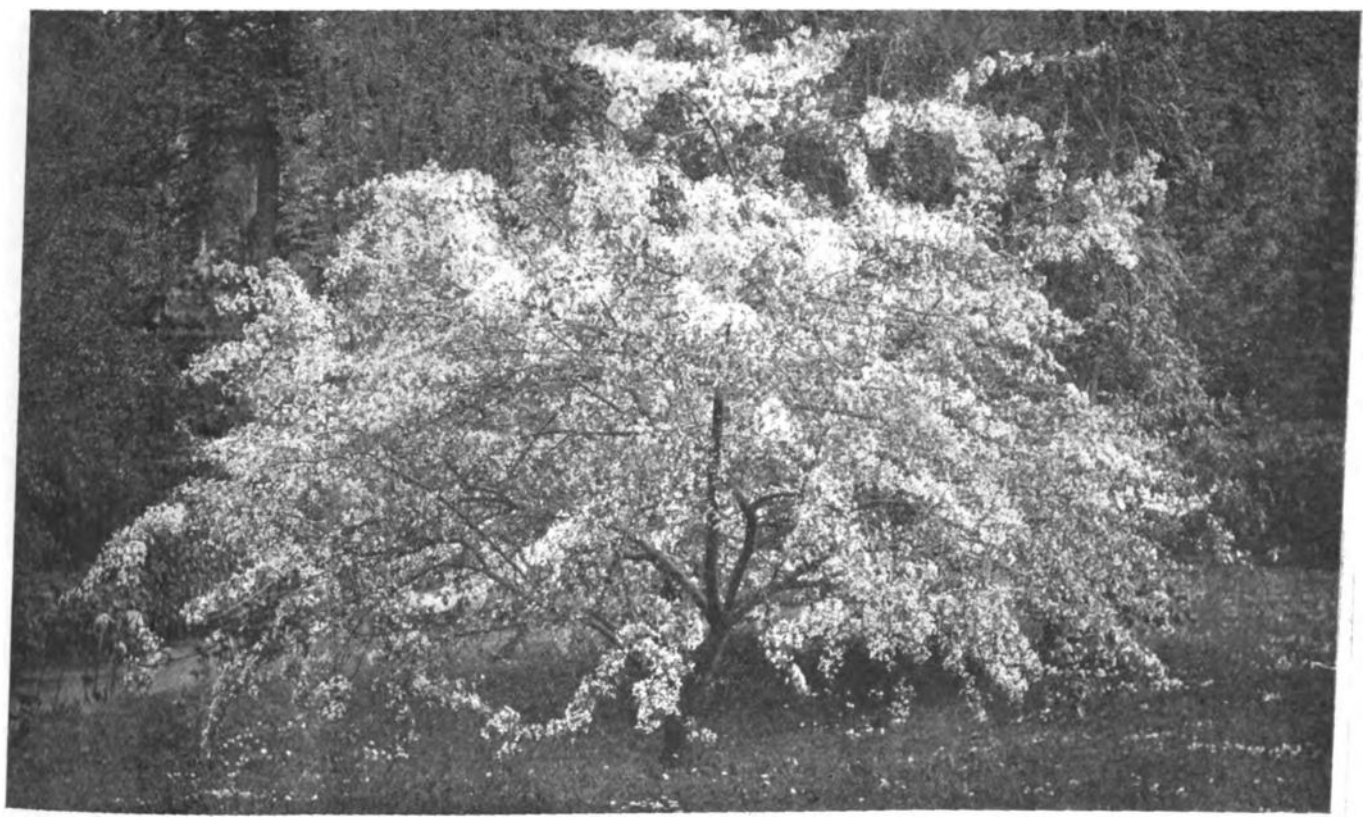
THERE is always something to instruct the garden lover at Kew, no matter what branch of the wide subject of gardening he may be interested in. It is from about the middle of April onwards through May to early June that Kew reaches the zenith of its beauty in the pleasure grounds, although this year the majority of things are about a fortnight or so before their time. This is also generally the most popular season, when visitors go to Kew in the greatest numbers.

The wild flowers in Kew Gardens are probably one of its greatest beauties and of them all there is none more charming than the bluebell of our woods. Masses of them carpet the ground beneath the trees and produce delightful effects in the Queen's Cottage grounds and in the woods on the east side of the lake through which runs the woodland walk.

In the rhododendron dell the large-leaved hybrids provide a succession of flowers for fully six months, beginning with Rh. Nobleanum in the first days of January. Throughout the month of May and during early June it is one of the most popular walks in the gardens. Limits of space prevent mention of even a small proportion of the vast number of named varieties, but because of such outstanding merit the hybrids of Griffithianum (Aucklandii) raised by the late Mr. Mangles cannot be omitted. They include Isabella Mangles, Daphne Daffarn, Dulcie Daffarn, Beauty of Littleworth, Coral Star and Liza Stillman.

THE AZALEA GARDEN.

Among the special features in the pleasure grounds at Kew few rival, and none surpasses, the azalea garden during May and early June. Originally planned as a garden for



A FINE PLANT OF PYRUS MALUS FLORIBUNDA, ONE OF THE BEST OF CRABS.

Nothing among the newer Chinese barberries equals Berberis stenophylla in flower. Planted in masses, the gracefully arching branches are covered with rich golden yellow blossoms. Its value as an evergreen flowering hedge is well seen surrounding the formal water garden. B. Darwinii is also a glorious flowering shrub, more upright in growth than the last named and with rich orange yellow blossoms.

The area surrounding King William's Temple is largely occupied by trees and shrubs belonging to the Natural Order Ericaceæ, among which the rhododendrons predominate. Several groups of Kurume azaleas, the progeny of plants raised from seeds collected by Professor Sargent, provide a feast of colour. Dwarf species, particularly valuable for the rock garden, include Rhs. impeditum, intricatum, scintillans, calostrotum, ledoides, Williamsianum, flavidum and Forrest's form of racemosum, as free-flowering subjects for beds. Rhs. yunnanense, rubiginosum, Augustinii, Davidsonianum, hippophæoides and yanthinum, are the best Chinese species.

American or ericaceous plants by Sir William Hooker in the early fifties of the last century, it was remodelled and enlarged by his son, Sir Joseph, in 1881.

The removal of the botanical collection of the Natural Order Ericaceæ to the neighbourhood of King William's Temple, left the area free for the development and extension of the beds of azaleas. Some of the best specimens of magnolias to be found at Kew add to the beauty and interest of this spot.

Words are inadequate to describe the gorgeous feast of colour and delicious fragrance, and, while the collection is kept fairly up to date by the addition of new varieties from time to time, it is the large old bushes which are such a prominent feature. Judged for delicate colouring, freedom of flowering and powerful fragrance, they would easily outpoint the newer sorts, only taking second place in the size of the individual flowers, the pointing for which should not be very high.

The surrounding trees of the azalea garden add considerably to the charm of the picture. Sprinkled among the young

Digitized by Google

tender green leaves of the oaks, hornbeams and limes are a number of copper beeches.

THE JAPANESE CHERRIES.

Early in May generally a considerable number of double and semi-double flowering Japanese cherries are conspicuous, planted in various parts of the garden. This year many of them were in full blossom in April. The largest number are planted on the lawn between the Palm House and King William's Temple. The low grass mound to which the name of "Cherry Mound" has been aptly given is now one of the beauty-spots of Kew in the flowering season.

The most beautiful of the whole collection is the variety "Kanzan" of the Japanese, the nursery name for which in this country is Hisakura (red cherry). The distinguishing features are its upright growth, rich double rosy pink blossoms, red in a bud state and young reddish brown foliage. The variety "Kirin" or James H. Veitch, does not differ much in flower from Hisakura, but the trees are readily picked out because of their spreading habit of growth. Sieboldii or Watereriana, is very free with double pale pink blossoms. Cheal's Weeping or rosea pendula, is a beautiful variety of pendulous habit with deep rose double blossoms. Serrulata albo pleno is very distinct, sending out long horizontal branches freely clothed in the season with double snow-white blossoms. Serrulata grandiflora or "Ukon," of the Japanese, has yellow tinted blossoms. Ojochin is one of the best sorts with single pale blush blossoms. Aman-o-gawa is deserving of a place in a collection because of its upright growth, like a small Lombardy poplar with apple blossom tinted flowers.

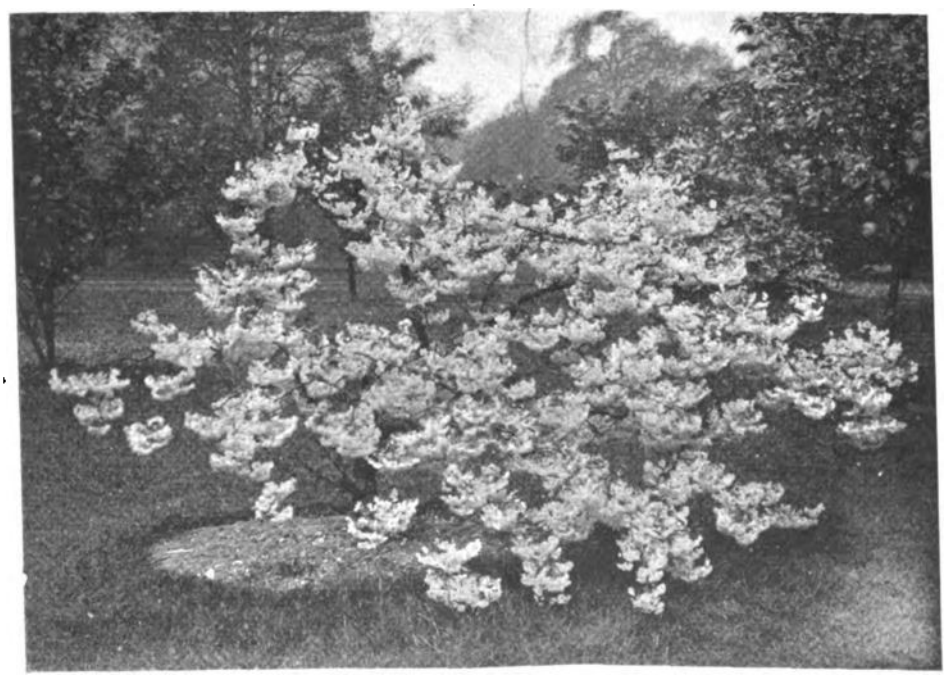
THE MALUS, OR CRABS.

As ornamental flowering trees the malus section of the pyrus family have few rivals. For grouping on rising ground, or with evergreens in the background, and as specimen lawn trees, they are very beautiful and effective.

A WELL-FLOWERED BUSH OF AZALEA MOLLIS.

Asked to name them in their order of merit, I should place P. Scheideckeri first, a hybrid between floribunda and spectabilis. The pale rose blossoms, often semi-double, are produced in profusion during the first half of May. P. floribunda, a large bush or small, wide-spreading tree, is very attractive when completely clothed with the delicate pale pink blossoms. In the variety atrosanguinea the flowers are deeper in colour, particularly in the bud state. The carmine or rosy purple blossoms of the Russian crab, P. Niedwetzkiana, are strikingly effective, in contrast with the pale pink, apple blossom tints of many crabs. Its value as a parent among the newer hybrid crabs is seen in P. purpurea (P. floribunda × P. Niedwetzkiana), a beautiful flowering tree with bronzed foliage and rich purplish rose flowers. Somewhat similar in growth and habit, P. Aldenhamensis has deeper coloured blossoms and is a fortnight later in opening. P. Arnoldiana may, perhaps, be best described as a large-flowered floribunda, a most beautiful and free-flowering crab.

P. spectabilis, rosy red in a bud state, opening to pale pink; the variety Kaido, with deep rosy pink blossoms; and Sargentii, with pure white flowers, also deserve special mention.



PRUNUS ROSEA PENDULA, A MOST GRACEFUL WEEPING CHERRY.

SERVICE FOR READERS

Though so many subjects are dealt with in each issue of THE GARDEN, it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our new Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, whether advice is sought as to—

RESTOCKING A GARDEN, COLOUR SCHEMES FOR GARDENS, THE BEST PLANTS FOR CERTAIN SITUATIONS, WHERE TO OBTAIN NEW AND RARE PLANTS, INSECT PESTS, NAMING OF PLANTS, AND THE HUNDRED AND ONE OTHER DETAILS RELATING TO THE GARDEN—

there is always information available from a staff of expert contributors and consultants; *and there is no charge for this.* It is one of the additional means of Service which THE GARDEN is glad to render to its readers.

All communications should be addressed to the Service Department, THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C.2.

Digitized by Google

THE GARDEN VALUE of the DAHLIA

AS a general rule, it will be found that the most satisfactory dahlias for the flower garden proper are those of medium and dwarf habit, and it is these which come into flower earliest and may be relied upon to bloom continuously until cut by frosts. When a blaze of colour is desired, Coltness Gem is, to most of us, the dahlia of dahlias and, except for the smallest flower-beds, will rise superior to the scarlet geranium so beloved of many summer gardeners. It is of dwarf, compact habit, needs no stakes, and, if the old flower stems are removed as soon as the florets drop, Coltness Gem will flower continuously in sunshine and in rain. As a companion, the value of Lemur is not yet fully realised. It is also a dwarf, free-flowering single. The flowers are a rich velvety crimson, and at all times its dark purple foliage is valuable. Piccaninni, of similar type and colouring, is one of the dwarfest of the dwarf dahlias. Aimée Barillat is another useful dwarf single, with bronzy foliage and glowing crimson scarlet flowers. Last summer a large bed of this variety at Greenwich Park was immensely admired. Little Jenny is a very pretty dwarf single.

Among the show singles there are many with delightful shades of colour, and, while they are not generally grown for garden decoration, they make splendid displays if the superfluous foliage is pinched out. Many dahlia enthusiasts, with reason, predict a great future for the mignon dahlias, which, after all, are singles under another name. The originals were raised in France, but our growers have lately paid increased attention to them, and, among others, Messrs. J. Cheal and Sons have introduced some valuable varieties. They have wisely aimed at dwarf, compact, free-flowering varieties, and in this have succeeded. The trial of the type which is to be conducted at Wisley this summer, under garden conditions, should be of great value. Among the newer varieties there are Canary Bird, of clear yellow colour; and King Cup, of deeper tone; with H. J. Jones, of larger size; Rosebud, salmon pink, tinted with rose; Paisley Gem, deep orange red; Blanche, pure white; and Ethel, deep crimson maroon.

Of rather taller habit, but still sufficiently dwarf for bedding purposes, are the miniature peony and small decorative dahlias. Except for exhibition purposes, they may well be classed together, and, in fact, some growers do this and term them "charm" dahlias, for they are very charming flowers. The best modern types become about 3ft. to 4ft. in height, and are compact plants producing astonishing quantities of flowers over a long period. As general purpose dahlias, they are ideal, and, in addition to great garden value, they are splendid as cut flowers. Already the market grower has realised their value, and last summer and autumn large quantities were sold in florists' shops and by hawkers in the streets of London. There are many varieties in all possible shades of colour, and in no other type are there such delightful colour associations as in these charm dahlias. Pink Pearl is a splendid example of the type, and one may easily have thirty to forty flowers open at the same time on a plant. Radium, raised by Mr. J. T. West, who has paid special attention to the charm dahlias, is a perfectly formed flower of brilliant scarlet colour, shading to orange in the centre. Hon. Mildred Campbell has a little more orange in its scarlet and is clear yellow in the centre. Lord Lambourne has a splendid upright habit, and its deep red colour is edged with gold. Sweet, a charming shade of pink, is a splendid cut flower. Of the many varieties grown at Hyde Park last summer the most admired was the pink and cream Velma. Mary, maroon; Nigra, purplish crimson with dark foliage; Wessex, deep crimson; May, yellow suffused with deep pink; St. Davids, a bright crimson scarlet; and Angelina, of coppery flame colouring, are the names of only a few of the delightful varieties of this type.

The larger-flowered varieties were well displayed at Regent's Park last summer, where, in a large border, many of the best varieties made a magnificent show. The best varieties have enormous brilliantly coloured flowers, borne on long stout stems well above the foliage. Among the newer varieties are Berengaria, of dwarf habit and orange colour shaded with gold; Sheila Ward is taller and of clear yellow tipped with white; Prestige bears plenty of large flowers of old gold shading. Border Perfection is rich scarlet; while Jean is a clearer tone. Reginald Godfrey, rich crimson; and La France, pink and gold, are also very free blooming; while Menny Carlée is one of the best whites.

Many who know only the older type of cactus dahlia hesitate to grow them, fearing they may have to search among the foliage for the flowers; but in the newest varieties such fears are groundless, for the best push up their flowers well above the leaves. Edgar Jackson is a lovely flower of salmon pink shading and very free flowering; La Lorraine is of old gold colouring; Mrs. E. Lowes is the best yellow cactus dahlia for the garden; Periscope bears out its name in habit and is of rich wine red colour; Miss Eckert is a pleasant pink and white; George Duncan is a broad-petalled cactus of salmon rose colour that is very effective in the border. Scarlet Glow does not appear to become much more than 3ft. in height, and bears plenty of brilliant flowers. Snowdon and Snow Bunting are good white cactus dahlias.

THE DECORATIVE VALUE OF VARIOUS TYPES OF DAHLIAS IN ONE BED.

In the garden, the collarette and the pompon dahlias are not always so successful as the types previously mentioned. They are apt to produce rather more foliage than many like, but this may easily be overcome by occasionally pinching out the superfluous shoots. There seems to be a prejudice against relieving dahlias of excessive growths, but as we regularly practise defoliation and disbudding with other plants there is no logical reason against it with dahlias. While most types of the dahlia yield best results from young pot plants set out early in June, it will be found that the pompons produce more flowers if the old tubers are saved and planted. These old plants are sturdier and distinctly more floriferous than cuttings. As cut flowers the collarettes have considerable value. Glen Sannox is a brilliant vermilion; Tyhurst is rich crimson with white-tipped quills; Lady le Bas is crimson maroon with white and crimson quills; Kingcup is a free-flowering self yellow.

For the garden one of the best pompon dahlias is Cheal's Bedder, which is of very dwarf habit and bears plenty of perfectly formed, carmine-tipped, orange bronze flowers. Bacchus, bright crimson; Daisy, amber; Little Beeswing, yellow, broadly margined with red; Mars, bright scarlet; Nerissa, soft rose; and Nero, the darkest of all, are excellent varieties. The star dahlias, first valued largely as cut flowers, are now also of considerable value for garden display, though they are the best of all for dinner-table decorations. Brentwood Star, cream and pink; Charlwood Star, fiery orange tipped with red; Crimson Star; Rusper Star, bright crimson; Salmon Star; and Shinfield Star, flame colour shaded with rose, are among the best of the new star dahlias.

THE FLOWER GARDEN

POPPY ANEMONES.

A Most Valuable Plant for Every Garden.

FEW hardy plants will so well repay the gardener for special attention as the poppy anemones. These glorious flowers are now to be secured in a range of glowing colours the like of which is not to be seen elsewhere. Now, although the poppy anemones will, if happy, grow "like weeds," it is most important, if complete success is desired, to observe one or two points. First of all, buy your roots from a good firm. Then you will make sure of getting a first-class strain and also get sun-ripened roots certain to yield the best results. It is worth while having a special bed for the poppy anemones. Anything in the way of a heavy, close soil will not suit the anemones, so that sand and gritty material should be worked into the bed where the ground is naturally cold. On the other hand, poppy anemones like a rich soil, always providing that it is well drained. The plants never do well unless they have plenty of sunshine, and it is a wise step to choose rather an open situation for the bed.

FOR BRILLIANCE OF COLOUR AND ATTRACTIVE FOLIAGE THERE ARE FEW BORDER FLOWERS MORE USEFUL THAN THE POPPY ANEMONE.

Probably not a few amateurs have been puzzled as to which way to plant the curious tuberous roots of the poppy anemones, and now and again, it is to be feared, these have been set upside down. This means that the stems have to pursue a roundabout course to reach the air, and, in many cases, they give up the attempt altogether and that particular plant dies. Examine the tubers closely and, near the centre, you will find a number of small protuberances known as crowns. These crowns are obtuse points often a shade darker than the surrounding skin. From these crowns the shoots arise, and they should always be upwards when planting is in progress.

Poppy anemones very much dislike a heavy shading of the ground even when they are not in active growth. On this account they often give poor results when in a border with other plants that extend on all sides. If well managed, a bed devoted solely to poppy anemones will be attractive for the greater part of the year. The principal flowering time is, of course, in the spring, but if the situation is fully exposed to the summer sun a second display of blossom is made in the autumn. Indeed, during a mild winter one may have poppy anemones into November. To ensure autumn flowering, let the bed dry up well in the summer. If any seed heads are forming, remove, as, if allowed to remain, they will very much weaken the tubers Keep the anemone bed quite clear of weeds and hoe lightly now and again. In such a position the tubers may be left for years and the show of flowers will astonish those who have never realised the beauty of the poppy anemones. The setting out of poppy anemones may be carried out at almost any time and there is no need to adhere to the autumn planting recommended in most garden books.

The single and semi-double poppy anemones are easily raised from seed. Excellent results follow if this is sown in the late spring or early summer. Choose a sunny position for the seed bed, mix the seeds with dry sand to separate them, and scatter broadcast on the soil which has been well raked. Cover the seed very thinly with fine soil and beat flat with a spade. It is a good plan to protect the seed-bed for about three weeks with sheets of newspaper held in place with a few sticks. Water freely if the weather is dry, and when the seedlings appear remove the paper. To encourage continued growth the bed should be kept moist all through the summer. The anemones may be left where they are or removed to other quarters in October. Many of them will flower well in the following spring.—S. LEONARD BASTIN.

LOOKING AFTER ANNUALS.

An Important Operation at This Time of the Year.

AT this time of the year there is so much to do in the garden that it is essential to fix in mind the most important things that demand attention. These are critical days in the lives of the annuals, and it is well to give them special consideration. Even the hardiest subjects require some attention if the best results are to be secured. Those annuals which have been sown where they are to remain will require thinning out so that each plant may have sufficient room to develop and exhibit its true characters. Any specimens which show signs of premature flowering are best removed, as these rarely do well. Weeds should be kept down and shoots from adjacent plants that tend to overshadow the annuals should be tied or cut back. Often at this time of the year we experience a spell of hot dry weather, and the clumps may suffer badly. A constant breaking up of the surface soil round the annuals will help them to withstand the drought. If this is done, the formation of a hard crust is prevented and there are none of those cracks through which moisture from the subsoil evaporates. Generally speaking, if the hoe is freely used, hardy annuals should not need artificial watering so early in the season. Any plants that require supports should be given these without delay, as rough winds may do a great deal of damage to the tender growths. A daily removal of withered flowers, to prevent seed setting, is essential if the plants are to keep up a display.

The tender growth of the annuals will prove very attractive to slugs. One of the best methods of fighting the pest is to place a piece of orange peel near each clump. Slugs seem to prefer the white part of the rind to any green thing that grows, and the plants will escape damage. The little wood-louse (Oniscus) is often a great nuisance. These creatures will creep into any dark place during the daytime and a few pots stuffed with straw and inverted on the ground will entrap the pest to such an extent that the ground is soon cleared.—B.

BEDDING OUT.

Useful Notes on this Important Subject.

IN the southern counties lovers of summer-flowering plants will be busy planting them from the last week in May until June 10th for the general stock and June 15th for the most tender subjects. In the northern counties the work may begin the second week in June and be finished about the 25th of that month. In every case the wise gardener will duly harden off the plants. To transfer tender subjects direct to an open border from the shelter even of a broken-down frame often means a serious check. The plants should have been without frame protection for at least one week prior to their full exposure in open beds. The hardening process should be very gradual. If this has been attended to then the work of bedding-out may be pushed forward as quickly as possible so that the plants may get well established in their new quarters before the subsoil becomes very dry in case a naturally dry summer follows. If, however, the hardening of the plants is not complete by the dates named, then it will be wise to defer the planting out one week to allow the stock to become harder in partly sheltered quarters.

SOIL MANURE.—If a quantity of blossom is required, then ordinary bedding-out stock must not be grown in a very rich soil. A naturally poor one must, however, be enriched to a certain extent. Abundance of blossom cannot be produced on puny plants. There is the happy medium, and so, if the soil is really a very good one, very little manure will be required. Soil deficient in humus should be enriched with rotted manure; failing such, use hop manure, such as Wakeley's. Very heavy soils will be improved if rotted leaf-soil and burnt rubbish from the garden smother fire be mixed with them. If very fine foliage is the chief object in view, then the soil should be well manured, but not with such stimulants as sulphate of ammonia or nitrate of soda.

Digitized by Google

The rotted manure, leaf-soil, rotted refuse and cool, concentrated manures applied as advised by the vendors will do nicely and produce the finest foliage.

THE PLANTS—FROM POTS AND BOXES.—More care should be taken with the plants taken from boxes than with those from pots. Plants grown in boxes and beds—and we have thousands of them in every district—must be lifted carefully from such quarters and be replanted at once with as much soil adhering to their roots as possible. In all cases the plants should be well watered a few hours before they are planted. There will not be any difficulty in regard to pot plants if the insides of the pots were clean and dry when first used. If they were dirty, then this timely watering will be beneficial. Planting several hours after a heavy rain is always pleasant work. If, however, rain is absent and the soil almost dust-dry, thoroughly soak it the night before planting.

BEDS AGAINST WALLS.—The soil in these is always drier than in open borders, so more attention to watering such wall beds should be given. It is well to study colours where red, grey or white walls are concerned, also colours in the open borders so that harmony may prevail, or good contrasts. This is, however, too big a subject to deal with in this note.

A FEW SALIENT HINTS.—Always have distinct edgings to medium-sized and large beds and none to small beds. Dot plants are much used: be sure that they are dot plants and not a forest smothering the ground-work plants. Do not use too many colours in one bed. Self-colours are generally pleasing, also shades of blue, and avoid too much white—it may create a coldness. Do all the work well; avoid skimpiness, also overcrowding.—GEO. GARNER.

THE CORN MARIGOLD.

A Native Plant Worth Growing.

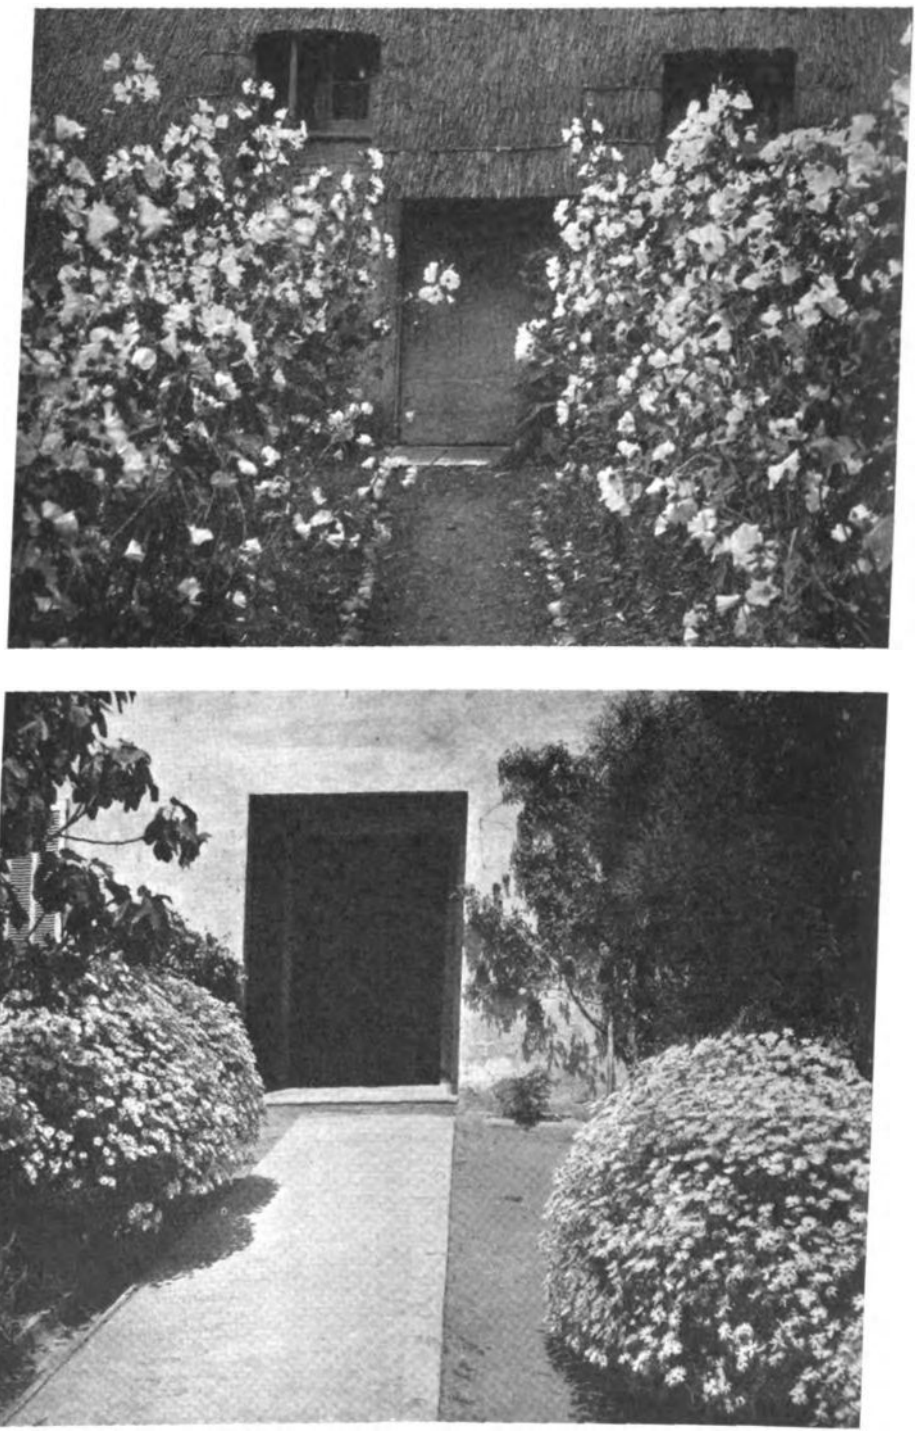
A CERTAIN number of British wildings have, in some form or another, found a place in the garden. It is interesting to call attention to yet another species which is well worth bringing into the cultivated area. This is the corn marigold (Chrysanthemum segetum), a species which, with the moon daisy (C. Leucanthemum), completes the list of native chrysanthemums. The corn marigold is a very strong-growing plant with long toothed leaves which tend to be glaucous. The flowers are like large daisies and of the most gorgeous yellow shade to be seen in the whole world of plants. Most botanical books describe the corn marigold as local, and there are certainly wide tracts of country where one might hunt in vain for a single plant. On the other hand, where it does occur it is usually very abundant, and in some parts of the south of England is regarded by the farmer as an obnoxious weed. As its name implies, the corn marigold usually grows in fields, or at least on ground where some kind of grain has been cultivated.

In a garden the corn marigold develops on very handsome lines, and it evidently thoroughly appreciates the protection it receives. It has one very remarkable characteristic, and that is the extent of its flowering period. The corn marigold is an annual with tendencies to prolong its life beyond a year. During this time it practically never ceases to produce its splendid flowers. The writer has seen the plant in bloom in every month, although it is at its best in the late summer and fall.

The corn marigold is not at all particular as to soil, providing this is well drained. It should be allotted a sunny position, and it is not a bad plan to give it a bed all to itself. Here the plants may be left undisturbed for years, and they will keep on sowing themselves and ensure the upkeep of a constant succession. To start the bed is a simple matter. Gather some of the ripe seed heads in the field, or better still, dig up young seedlings. Scatter the seed over the soil or set the young plants a few inches apart and your bed of corn marigolds is sure to be a success.

WHEN THE BULBS ARE OVER.

WITH the increasing heat of the sun the foliage of the spring-flowering bulbs begins to wither. Flower stems which are setting seed should be removed, as the process involves a serious weakening of the bulb. At all costs resist the temptation to cut away the leaves, as these are developing food material for storage in the bulb. Only when the leaves are withered, and can be pulled away without effort, should they be removed. With the exception of snowdrops, all the common spring bulbous plants may be lifted towards the end of May, and some of them are the better for it. Good results always follow the replanting of crocus bulbs—or



THE PATH TO THE DOOR IS ALWAYS IMPORTANT. WHEN PLANTING STUDY THE EFFECT AS IT WILL APPEAR TO A PERSON WALKING DOWN THE PATH TOWARDS THE HOUSE.

To those who hesitate to introduce a weed into the sacred precincts of the garden, it may be pointed out that the corn marigold is quite a safe plant to grow. Curiously enough, it does not seem to spread very much in a garden, and is certainly not more likely to appear in unexpected places than many of our well known hardy annuals.—L. B.

Digitized by Google

corms, as they are more properly called. Here the new corms are formed on the tops of the old ones, and in course of time the plants will almost force their way out of the ground. The result of this is seen in the small, poor flowers that come with the following spring.

Where, as sometimes happens, it is wished to clear a border of bulbs which are still growing and green, it is worth while digging them up and planting them in some odd corner where they can complete their development. As soon as the tops have completely died down the bulbs are dug up altogether and stored in some dry place. The Dutch growers keep their bulbs during the summer in sunny sheds, and there is no doubt that warmth and light help to ripen the bulbs and ensure fine flowers during the following season. Never, as is sometimes done, throw bulbs in a heap in some damp corner, as many of them will probably rot and those that do not will be flabby and not hard as a properly ripened bulb should be.

All the spring-flowering bulbs are worth keeping. With reasonable care narcissi and tulips will be as good the second season as they were the first. Hyacinths usually deteriorate, and after one year's growth in Britain could not be classed as first-rate bedding bulbs. If the bulbs have been well ripened, the blossoms, although somewhat smaller than the original ones, are quite good. It is not a bad plan to have the old and small hyacinth bulbs all put together in some bed where they will yield a most useful supply of cut flowers in the spring.—S.

SOME DWARF BOG PLANTS.

A Short Selection for Present Planting.

THIS is the best of all seasons for planting many of the summer-autumn bog plants, and the following are a few suggestions among the smaller ones of these which I consider of the highest merit, taking ease of culture into consideration.

Among the indispensable mimuluses, M. Whitecroft Scarlet, in glowing orange-scarlet; M. Croftonianus, so distinct in cherry crimson; and the gorgeous little Coronation, are a trio of the most brilliant. To these I would like to add the lovely M. Lewisii alba, but its winter-worthiness has not been fully tested here.

Gentiana septemfida and G. Lagodechiana having proved such splendid doers in bog, we now never grow them anywhere else but at the brink of the water. A good form of G. Pneumonanthe put into damp ground along with a few clumps of Parnassia palustris have among them patches of Wahlenbergia hederacea and Anagallis tenella. These adorable little natives go admirably in double harness, and among other lowly carpeters which come to mind are Veronica repens, with almost white flowers nestling in its deep green mats; and V. canescens, whose moss-like growth is flecked with china blue during the later summer. Mentha Requieni will make its appeal for a like purpose. Myosotis Rehsteineri is a cushiony forget-me-not, and in selecting a form of the useful M. palustris for ranging the wider areas I can recommend var. stabiana.

Pinguiculas, especially P. grandiflora and the rosy P. Reuteri, are mudland dwellers of the utmost charm, and among the bog-loving saxifrages, S. aizoides atrorubens, S. stellaris and the much bigger S. aquatica can be planted with confidence. The waxen, flesh-pink flowers of the annual Sedum villosum are as attractive as the foamy inflorescences of the beautiful S. pulchellum, which never does so well as in wet soil.

In the matchless azure of its pea-flowers, Parochetus communis is supreme among the later dwellers of the waterside, and ninepenn'orth of this delightful trailer no one can afford to be without. Spiræa digitata, Astilbe crispa and A. simplicifolia comprise a trio of the choicest of dwarfs, and to each of these astilbes some distinctive varieties have recently been added. Silene alpestris is a wet ground plant of the highest merit which is not often seen at its best in drier places.

The hybrid calceolaria John Innes is a really good plant for the warmer parts of the bog, and a similar spot should suit the brilliant Ourisia coccinea, which, if not exactly amiable in my garden, is easy and pleasant in others. Lovers of the curious will find Sarraccenia purpurea a profitable investment, these pitcher plants having blossoms and leaves of striking colour and form in addition to a taste for midges. Finally, I would put in a plea for Polygonum vaccinifolium, which can be extremely beautiful in later summer, tossing its rosy billows over some stump or boulder at the edge of the bog or waterside.—A. T. JOHNSON.

THE GREAT CHELSEA SHOW

May 25th to 27th

THE great Chelsea Show of 1926 is a triumphant success, contrary to the expectation of many prophets of woe who said that the strike and the weather in evil combination would probably make a failure of it. Their Majesties the King and Queen have again honoured the Show with their presence.

Every year the same remark is made that "This is the best Chelsea Show." This year it can be said with even more justification than usual. Each exhibit is as good as it can be—so good that the judges have had a difficult job to place them in their order of merit. The R.H.S. certainly deserve every credit for the way in which the Show has been arranged under grave difficulties. Everybody has worked hard, and it is now up to the general public to support it.

Two innovations are to be seen this year, one a special tent for pictures and paintings of gardens, the second, a very wise one, that the orchid tent is confined to orchids and other greenhouse and stove plants. One criticism has to be made, and that is that much of the canvas in the roofing of the tents is so thick and so grubby that it seriously impedes the light. Under the circumstances, it has been impossible to illustrate in a satisfactory manner all that we should have liked to have done. It is to be hoped that this is a fault that will be remedied next year, for ample lighting is an absolute necessity for showing off such magnificent colour displays, particularly in dull weather.

FORMAL GARDENS

In spite of the many difficulties with which the horticultural world has had to contend, the formal gardens are certainly one of the most attractive features of the Show. Restrictions in transport do not seem to have made any appreciable difference to the quantity of material used, for there are plants and stone in plenty. Some of the garden architects have had to modify their original plans. Still, the formal, as well as the rock gardens, reflect great credit on the various exhibitors, and they are quite up to their usual high standard of excellence.

The lay-outs are most varied in design and adaptable for reproduction in numerous sites. Some gardens are complete in themselves,

MESSRS. CARTER'S "GARDEN OF REFLECTION."

Digitized by Google

while others show a method of treatment suitable for a portion of a large garden. Among the latter type Messrs. J. Carter and Co. of Raynes Park illustrate a very effective planting of a woodland glade. This "garden of reflection," as it is called, is a blaze of colour and yet restful. The sombre conifers which surround the garden give it its woodland setting, and the waterfall which gently trickles down over mossy slabs of water-worn limestone drips into an irregularly shaped pool beneath. In the middle of the pool there is a low-lying island with a few shrubs growing on it. This and the pool are most natural in outline. The marshy ground rises fairly rapidly, and on sloping banks are planted countless crimson and pink rhododendrons. Fine specimens of both standard and bush rhododendrons are reflected in the pool below.

Messrs. Cheal and Co. of Crawley have designed an imposing formal garden on a large scale. Almost half the garden is sunk and paved with stone. In the centre of this part there is an octagonal pool surrounded by shaped beds filled with some of the best varieties of the increasingly popular Mignon dahlias. Such varieties as Etna, Albion, Grace and Coltness Gem are noticeable. Conifers and flowering shrubs form a background for the garden, and immediately in front of these are beds of soft pink herbaceous spiræas. At the other end of the garden a feast of colour is produced by beds of the many-hued azaleas, rhododendrons, standard brooms (such as Cytisus præcox alba) and the fresh green foliage of some of the acers. Quaintly clipped yews are stationed at regular intervals on each side of the paved centre path.

The garden of Messrs. Gazes of Kingston-on-Thames is most original in style, and could quite aptly be termed a "moat garden," for the rectangular central portion is almost completely surrounded by a moat. It is not easy to give a true idea of either the design or colouring of this garden. Even the stones in the cobble-stone path beside the moat vary greatly in colour, and the odd pieces of brick and bluish slate in the retaining walls make a pleasant contrast against the cascades of alpines flourishing in the wall crevices. Lupins in pinks and blues are the predominating plants of the outer borders. The terraced end of this garden and the steps leading up to it are particularly well designed, while the pillared shelter is in keeping with the whole scheme.

A well thought out and carefully constructed garden has been arranged by Messrs R. Wallace of Tunbridge Wells. The centre space is of elliptical design (a somewhat unusual treatment), sunk and paved. In the middle of this is an oval mirror pool, and near by are clumps of irises and funkias. A circular path leads one through beds of azaleas, rhododendrons and Japanese maples and then up to an artistic thatched roof summer-house. From this aspect, particularly, the beauty of the garden can be well appreciated. The shrubs are of most vivid colouring, and yet each colour is so placed that it does not clash nor strike a hard note with any other shade. Crimson rhododendrons, such as Douglas and Peter Koster, have been separated from varieties of bluish pink or mauve.

Skill and ingenuity have been used by Messrs. Bakers of Wolverhampton to erect their formal garden. A wide clipped yew hedge fashioned in festoons and pillars borders it on all four sides. A paved walk leads from one level to another, and on the higher level there is a fountain figure. A stone seat is placed in each of the two yew arbours, and at one side a garden shelter constructed entirely of Bath stone is attractively draped with Wistaria sinensis. Pink lupins and purple irises in the borders stand out well against the dull green background of yew.

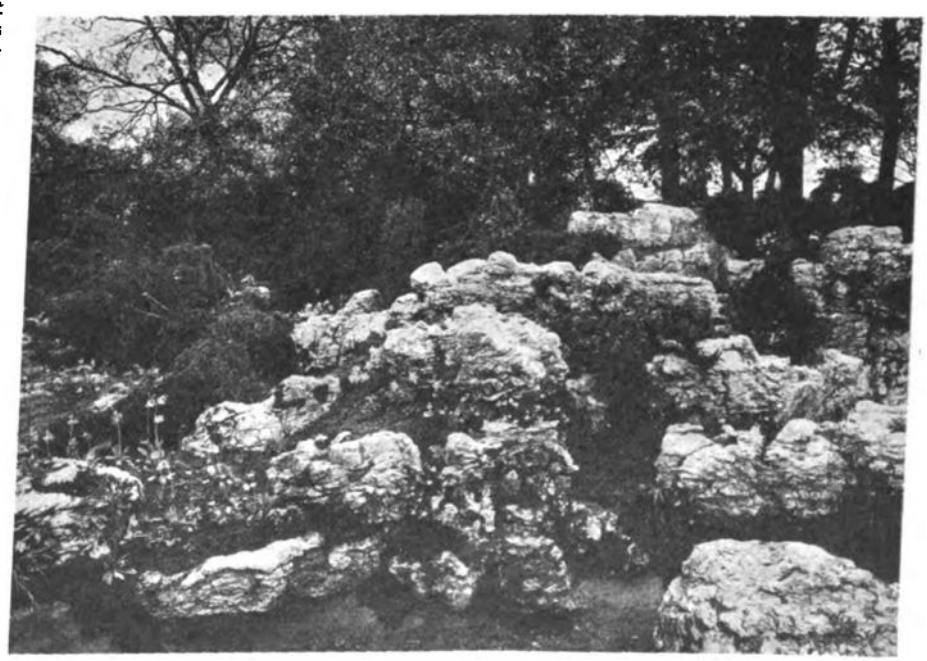
The white pillared pergolas which flank the garden of Messrs. Vernon Brothers remind one of the blue Mediterranean and its sunny gardens. The central feature is a sunk paved area with two long, narrow, rectangular pools running side by side. Fountains are playing, and the pure white lilies in the surrounding borders are gleaming in the sunlight. Pink and crimson rambler roses bedeck the pergola pillars. Paving of various styles in stone and brick is here displayed, and the top of a low dry wall is crowned with a tumbling mass of a white-flowered mossy saxifrage. The leaden figures used to ornament this attractive garden are of great beauty.

Again this year the famous grass seed specialist, Mr. Macdonald of Harpenden, has arranged a formal grass garden. It takes the form of a vivid green velvety lawn set with beds of tall grasses.

There are several gardens which could be erected just as they stand on quite a small site. Mr. Ernest Dixon's (of Putney) garden would be very suitable for any suburban garden, and it has the merit of being filled with plants which would prove attractive for a number of months during the year. Two crazy paved paths cross the garden at right angles, and at their meeting place there is a small sunk portion and a sundial. Along all sides narrow borders of hardy herbaceous plants are backed by a fence enclosure of osier hurdles.

Another small and well proportioned sunk garden has been designed by Messrs. W. Wood and Sons of Taplow. The value of square oak trellis as a fencing as well as a pergola are shown in this garden. A central oak pergola beneath which an edging of nepeta is growing leads one up to the attractive little sunk garden with its pool.

A PORTION OF THE "CLIFF" IN CAPT. SYMONDS JEUNE'S ROCK GARDEN.



A VIEW IN MESSRS. CLARENCE ELLIOTT'S ROCK GARDEN.

Digitized by Google

brightly coloured flower-beds and spacious summer-house. Rhododendrons fill the borders, and alpines nestle in the cracks of the retaining walls.

Messrs. R. Neal and Son of Wandsworth have designed a garden where rhododendrons, azaleas and irises are the chief flowering plants used. A wide paved path cuts through the middle of a lawn, and on either side long borders are planted with dark purple irises. Beds of rhododendrons in all colours divide the lawn from a sunk fountain pool around which the colour scheme is mauve and purple. The best view of this garden is from the stone seat placed on a terraced portion at the far end.

The beauty and utility of natural stone are well illustrated by the formal garden constructed by the Horsecombe Quarries and Stone Works, Combe Down, Bath. A

MR. G. G. WHITELEGG'S CHARMING STREAM GARDEN.

stone balustrade surrounds it, and the central feature is a large vase placed on a raised pedestal. Every stone seat used, each vase, bird bath and ornament is of excellent design and yet varied in outline. Pink rhododendrons fill the vases and encrusted saxifrages flourish at the base of the pedestal. The grey colouring of this Somerset stone harmonises well with flowers of every tone. Particularly attractive is the effect when used in conjunction with a special colour scheme.

Messrs. Reamsbottom's famous St. Brigid anemones are again used in a small formal garden, and give a striking splash of colour. The owner of a seaside bungalow or a week-end cottage will be interested in the garden of wattle hurdles and the garden furniture made by the Rural Industries, Limited, of Cheltenham. The shelters and chairs made by the T. and C. Associated Industries, Limited, of London will also appeal to them.

ROCK GARDENS

The art of the rock gardener at Chelsea is so successful in concealing the labour and giving an impression of rest and stability that we are apt to forget the titanic work of piling up the boulders, the anxious preparation and the careful artistry of which we enjoy the result. But the dislocation of transport, by the strike and the doubt, at one time whether the Show could be held at all, turned our attention to the extra difficulties which the builders of the rock gardens would have to face, and it seemed beyond reason to expect that their exhibits could approach the usual standard of size and excellence.

Yet here they are, not only in their old form, but actually rather finer than last year. The boulders are larger than ever, there is more individuality in the designs, and there is less of the "bedded-out" effect which has so often concealed the beauty of the general scheme.

Every visitor, however critical, will feel inclined to congratulate the exhibitors on the courage and perseverance that have triumphed over exceptional difficulties.

The garden which stands out most strongly is built by Captain B. Symons Jeune, the garden architect. It achieves the supremely difficult ideal, now almost abandoned, of the old "Alpine garden," for it is a picture—yet by no means a mere reproduction—of a piece of alpine scenery. The central point is an abrupt peak of cleft and splintered rock with one sheer and almost vertical face. It overhangs a small dark pool and is balanced by a large hummocky boulder on the farther bank. The beauty of line is so satisfying that flowers are scarcely needed to enhance it, and the garden has been wisely planted with the greatest restraint. The austerity of the peak itself only allows a few dark sedums and a Lantoscana saxifrage moulded into a vertical cleft. The foreground is occupied by a real "alpine mat" of Globularia antenaria, gentian, androsace and thyme; and the pool is bordered by Iris cristata, Primula luteola, Viola pedata and other choice plants completely appropriate to their place. On the summit of the peak (but invisible from in front) is a gay patch of high alpines, Aster alpinus, Dianthus neglectus, etc.

Another garden of character is built by Messrs. Clarence Elliott of Six Hills, Stevenage, who take the conventional theme of waterfall, stream and pool, and handle it in a very individual way. The background is a forest of dwarf conifers, not used as a foil for patches of colour, but allowed to assert their own peculiar beauty, lightened by a few clumps of the milk white Anemone sylvestris. The rocky margins of the pool are set with real alpine plants. A group of Trollius pumilus, Primula sikkimensis and P. pulverulenta make a bold and very successful colour group of pale yellows and magenta. Lilium rubellum leans out over the water of the pool, in which a little rocky island is given over to the deep violet butterwort, Pinguicula grandiflora. On one side of the garden is a grove of the dwarf columnar juniper and a magnificent clump of Aquilegia glandulosa, both of them well known specialities of the nursery. The exhibit is labelled, in a way that would have pleased Francis Bacon, by six turfy molehills.

In the garden of Messrs. Herbert Brook the stream flows quietly in a series of pools through an alpine meadow studded with boulders and the orange suns of Arnica montana. The rocky banks of the stream are quietly planted with groups of trollius and Iris sibirica, whose dark red buds stand out pleasantly against the pale yellow. A fine plant of the rare Cupressus tamariscifolius hangs its flat feathery branches over one of the pools, and masses of Saxifraga pyramidalis foam out over the source of the stream.

Messrs. Hodson of Nottingham have made a pleasant little stream and terrace garden of ripple-marked limestone whose pattern is a little monotonous, though the general effect is soft and restful. The terraces are brightly planted with mossy phloxes and geums, while Ixiolirion Pallasii provides an unusual wistaria lilac.

In Mr. G. G. Whitelegg's very large garden the stream issues from beside a mass of rock of interesting but slightly top-heavy design, and wanders across a stretch of boulder-strewn turf. The banks are planted with broad stretches of violas, Primula Mooreana and Lithospermum Heavenly Blue. On the right-hand side of the garden a moraine set in turf does not associate very naturally with the rest of the picture, but provides a background for Oxalis adenophylla, Morisia hypogæa, Mazus repens and other small plants.

Captain Crewdson-Day has a pleasant little garden with a straight stream and small round pool, the whole discreetly planted with thrift, thyme, helianthemum, etc.

Messrs. Pulham have a garden in which the stream tumbles out of a dark cavern in the centre of shelving terraces brilliantly planted with geums, azaleas and Cheiranthus Allionii which shade down to quiet, low-toned pinks in the foreground.

At one end of the series of gardens, Messrs. Gavin Jones of Letchworth have a little mountain path between an outcrop of rock and a shelving cliff, both of which are jewelled with interesting little plants. Oxalis chrysantha, a wood sorrel whose butter yellow flowers harmonise perfectly with its pale bronzy foliage; a compact form of Veronica rupestris (V. Spode Blue), with flowers of a peculiarly soft shade of china blue; Lithospermum Frœbelli, a tuft of upright rosemary leaves and croziers of pale, iridescent blue; the deeply spotted Saxifraga caterhamensis; Dianthus neglectus, and many others.

At the other end of the row, Messrs. Cutbush's garden provides a complete contrast. A stream, soberly fringed with ferns, falls into a little pool whose surroundings are planted with vivid, post-Impressionist combinations of colour. The magenta red Primula pulverulenta beneath a standard wistaria; P. Red Hugh in various shades of flame colour, against the bluish green leaves of Funkia glauca; the whole in a setting of reddish sandstone. A very interesting example of a conventionalised rock garden.

TREES AND SHRUBS

As always, trees and shrubs play a great part at Chelsea. Although this year, owing to the vagaries of the weather during the last two months, the actual blossom may not be as fine as usual, there is no doubt that the exhibits show the same quality and excellence of cultivation as formerly.

Messrs. Cuthbert are staging one of their usual fine exhibits of azaleas in a corner of

Digitized by Google

the main tent. The colours seem even finer than usual. Coccinea speciosa certainly stands out, a brilliant coppery-orange, while of paler shades Sybil, a pale orange; Irene Koster, a blush pink occidentalis, and Daviesii, a creamy-white flushed with green and yellow, are charming. This firm can certainly call themselves azalea specialists. They also show two attractive shrub borders outside, where the bright colours of azaleas are shown off by the deep bronze foliage of maples, the lilac of wistaria and the yellow of laburnum. In addition they show excellent clumps of fine flowered forced hydrangeas.

Messrs. Wallace have a fine clump of rhododendrons and azaleas as a background for their lilies and irises. Among them Helen Schiffner still stands out as one of the best whites and Corona as one of the finest of all rose shades. Another good white is Mrs. Lindsay Smith, with large flowers and a big, upstanding truss.

Messrs. Den Ouden are showing a new hybrid rhododendron, Mrs. P. den Ouden, a deep rose, that is stated to have stood 32° of frost in the U.S.A. without flinching.

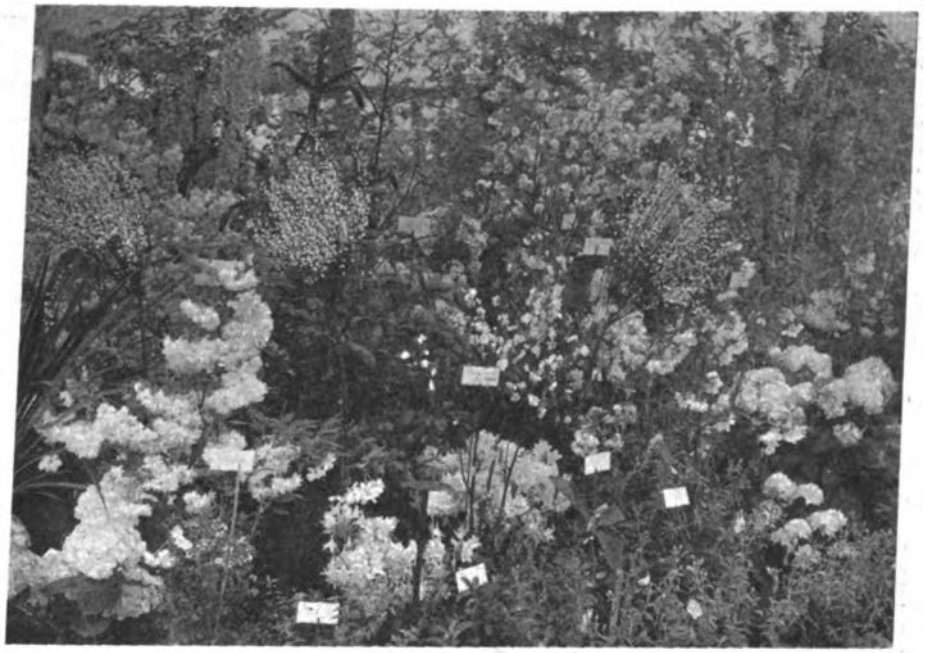
Mr. T. Lewis has a well flowered exhibit of rhododendrons and azaleas. Cynthia and Lady C. Mitford are excellent, the former deep rose, the latter a pale pink.

Mr. Reuthe, so well known for rare shrubs and rhododendrons, confines himself this year mostly to hybrids in rhododendrons—such as Doncaster, Corona and the fine loose-trussed blush white George Hardy. Among the shrubs, Enkianthus campanulatus albus is a pleasant creamy white form of this attractive shrub. Fine specimens of the ordinary form are also shown.

Messrs. Cheal show a particularly well grouped collection of rhododendrons and cytisus, along with a few hydrangeas, lilacs, maples and other ornamental shrubs. The selection is excellent and the grouping could not be bettered.

By retarding growth, Messrs. Hillier are able to stage an extraordinary collection of flowering cherries, along with other flowering shrubs. Prunus serrulata Sekiyama is most striking, with large, semi-double flowers of a good soft pink, while of the whites, P. Lannesiana Sirotæ, a large-flowered single, is excellent. Between the two in shade comes P. serrulata Ojochin, of the palest shell pink with a dark eye. If you want a yellowish tinge, look for P. Lannesiana grandiflora. Altogether this is a notable exhibit.

Along with giant eremuri Mr. J. C. Allgrove shows good specimens of maples and hybrid cytisus in pots.



SOME OF MESSRS. HILLIERS' FLOWERING CHERRIES AND OTHER ORNAMENTAL SHRUBS.

Mr. Notcutt shows standard cytisus in pots along with a few maples and azaleas. Among the brooms, Cornish Cream, is very aptly named; fulgens, a rich brownish-crimson, and the well known bicolor Andreanus, are noticeable.

Ornamental trees and shrubs are staged by the Donard Nursery Co. Ceanothus, veronicas, cytisus, maples, are all to be seen. One of the rarest of plants to flower is Grevillea thyrsifolia, deeper in tone than the ordinary G. rosmarinifolia and a finer plant. The former grows upright, whereas the latter creeps. The scarlet tubes of Embothrium coccineum are most vivid even in the dullest light.

Mr. Charles Turner shows maples, thorns, and lilacs, for the last of which, of course, he is famous. Jeanne d'Arc, a good white double, and L'Oncle Tom, an even richer L. Spath and of similar appearance, are the most conspicuous.

The Yokohama Nursery Co. stage their usual collection of dwarfed conifers and maples, along with a few Kurumi azaleas.

Messrs. Fromow again show their collection of Japanese maples, variegated and plain, in pots. As always, they show extraordinary cultivation and could hardly be bettered for quality.

By the main entrance gate is Messrs. M. Koster's show of rhododendrons and azaleas. Hugh Koster certainly stands out as a fine trussed, good crimson rhododendron, with flowers that are shapely and easily seen. Of the azaleas, Koster's brilliant red is certainly prominent as a magnificent flame colour.

Messrs. Charlton have an outside show of ornamental trees and shrubs. The cytisus are fine. A number of rare plants, unfortunately of doubtful hardiness, are included among them, the well known Billardiera longiflora, with greenish tubular flowers; the rare Australian hazel, Pomaderis opetala, and Decaisnea Fargesii, a very handsome foliaged shrub with long racemes of yellowish green flowers. This last is hardy, but liable to be cut.

One of the stands of Messrs. Waterer Sons and Crisp is filled with hybrid rhododendrons of such well known kinds as Pink Pearl, Bagshot Ruby—still one of the best crimsons—Gomer Waterer, a very pleasant blush pink with yellowish markings; Sappho, a white with purple markings on the upper segment. This firm's Mother-o'-Pearl, a newer introduction, improves every year. The truss is so excellent in shape, the colour, a soft pale pink, is so well set off with the rose stamens, that it is a most aristocratic looking plant.

Messrs. Hollamby's stand of ornamental trees is noticeable for very fine specimens of Acer palmatum atropurpureum and the cut-leaved form, dissectum purpureum. The colour in both is very good. Among many interesting conifers, they show Cryptomeria japonica alba spica, a curious form with pure white young foliage.

Messrs. W. and J. Brown show spikes of well known lilacs, such as Mme. Lemoine, that fine white double; Congo, one of the richest of the dusky red singles; and Jan van Tol, a newer variety, with large white flowers.

Messrs. Gill manage to stage an amazing amount of rhododendron flowers, considering that they come from Falmouth. Naturally, at this time they are mostly hybrids, such as the invaluable light orange yellow Azaleodendron Smithii aureum and a not unpleasant lilac-white cross between Aucklandii and ponticum. Among shrubs on their stand, pride of place must go to Olearia myrserioides

A SMALL CORNER OF MESSRS. BUNYARD'S IRISES.

Digitized by Google

with dark green foliage and a wealth of star-like white blooms with an orange centre.

Messrs. L. R. Russell, Limited have an outside stand of ornamental shrubs. For those who live in the extreme west, Metrosideros floribunda is interesting, with its bottle-brush flowers of red-purple, but it is a tender morsel. Among other plants are maples, Cytisus pallidus and the well known red Dallimorei; and the two Corokias, Cotoneaster and virgata.

Mr. H. Hemsley also has an outside stand of hybrid rhododendrons and foliage shrubs, such as Cupressus Fletcheri and Euonymus latifolius albo variegatus.

Messrs. Cutbush, Messrs. Klinkert, Messrs. Harrods and Messrs. Robt. Green all show topiary work.

IRISES

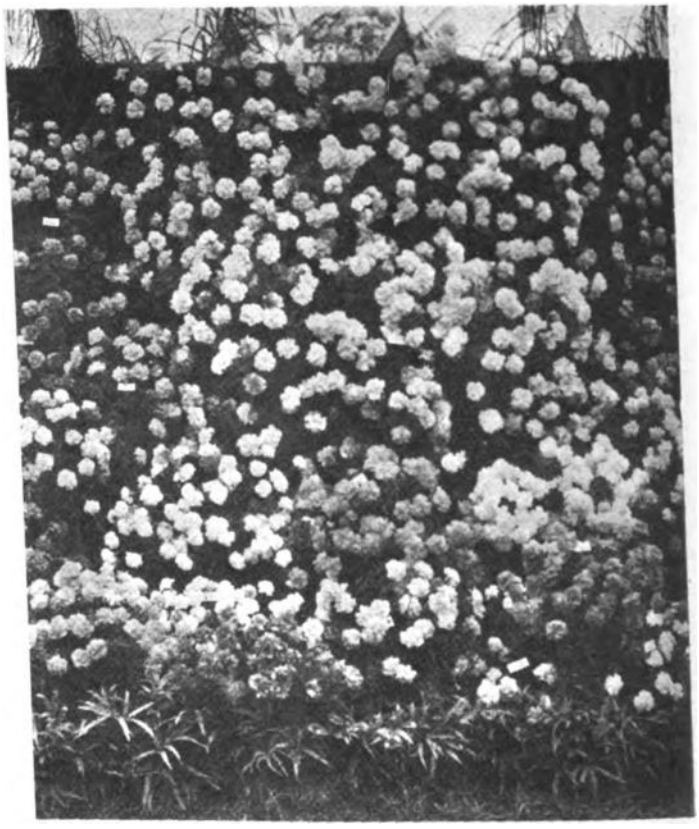
The season has been a fairly early one and that fact together with the postponement of the Show, did not augur well for a brilliant iris display, but it is here and fully up to the standard of its predecessors. The iris is not a flower which lends itself to exhibition work, especially under canvas. The lighter toned varieties lose much of their delicacy of colouring when seen under canvas.

One of the most charming and restful spots in Tent B is the iris garden of Messrs. Bunyard's. The whole arrangement is admirable and worthy of the highest praise, as it shows a keen understanding of how irises are best to be seen and appreciated. Laid out in groups, the central one diamond-shaped, and four surrounding this half octagonal, the plants are placed in slightly raised, naturally formed beds, so that they can be looked down on and the full beauty of the bed as well as of the individual varieties appreciated to the full.

Among the most notable varieties are the true free flowering and elegant Ambassadeur with its dark brown falls; Susan Bliss of delicate pink colouring; the pale mauve and sweetly scented Bullevine; and that very fine and wonderfully free-flowering variety, Souv. de Mme. Gaudichau, which is probably the best self deep violet purple iris there is. Among the red-toned irises—which are now coming into much favour, Medrano of a curious dark red, almost maroon, was conspicuous. Some of the older varieties are also present, many still without a rival in their respective colours. This is noticeably the case in the violet blue, where such old and popular varieties as Princess Beatrice still head the field. There are many others to be seen in Messrs. Bunyard's display, such as Mme. Schwartz, Paladin, Titan and Sapphire, all of fine form and habit and all well worthy of due attention by every keen iris lover.

Mr. Amos Perry does not stage as fine a display as usual, but there are many interesting varieties to be seen in his stand of general herbaceous plants. One or two very fine Ciengialti hybrids are on view, of which Ammon is one of the best, of a pale violet blue colour. Others to be seen are Silver Queen of a porcelain blue; the pale lavender Duke of York, dark toned Lord Lambourne of stately splendour, with its dark purple falls and the elegant lavender blue Mrs. Marion Cran.

From the nurseries of Messrs. De Goede Bros. in Holland there comes a pleasant little exhibit of xiphium irises in vases, with one or two striking sorts, including the bright yellow Van der Helst and Hutchenburg, most outstanding, with its bright rich golden yellow falls and standards almost white. The yellows stand out well from the pale blue and lavender tones of other varieties in the exhibit.



AN ENORMOUS CLUMP OF CARNATION LADDIE ON MESSRS. ENGELMANN'S STAND.

The Orpington Nurseries once more stage a fine display, arranged to reveal the merit and beauty of the individual sorts, rather than the effect in the mass. Quite a number of new seedlings are on view, all of fine form. Notable varieties to be seen are the handsome pale blue pallida dalmatica; the elegant Aphrodite, one of the late Mr. Dyke's introductions to the iris world, and Tenebrae, which originated in 1922 and is a handsome variety with its dark velvety purple falls. Another recent introduction on view is the June-flowering Duchess Sarah, a fine upstanding plant of good colour and habit. Many older varieties are also present, almost all mid-season flowering kinds and all are worthy of attention.

Messrs. Wallace's do not have such a fine show as is their wont. No doubt the earliness of the season accounts to some extent for it. Nevertheless, those that are on view illustrate that there are still as good irises coming from Tunbridge Wells as formerly. Some dainty varieties are laid out in a slightly raised bed to be viewed with advantage and display a fine colour harmony. One gets a rare idea of blend in colour and variation in height by looking along this miniature grove. The most outstanding of the varieties are Sweet Lavender, whose name is true to its colour; the mauve purple Florence Wills; Mrs. Valerie West, with its velvety maroon falls; and Souv. de Mme. Gaudichau, of good colour along with Kashmir White.

In Messrs. Barr's tulip exhibit a number of iris varieties are on view and the colours, the yellows and blues especially, are well blended. The Duchess of York, a fine pallida variety, is in excellent condition, while Souv. de Mme. Gaudichau and Iris filifolia are also good. The violet blue Imperator, a giant xiphium variety, shows up to advantage as a background to a few of the more dwarf yellows, including Van der Helst and Huchtenburg.

A very fine collection of seedling irises in the best of condition is staged by Mr. G. G. Whitelegg. There are close on five hundred spikes shown and each commands attention for its sterling worth. The ferns supply a pleasant touch of contrast in colour.

MESSRS. JACKMAN'S FINE EXHIBIT OF CLEMATIS.

CLEMATIS

Quite one of the features of the floral groups in the tents was the magnificent bank of clematis set out by Messrs. Jackman of Woking. The name of this firm is almost synonymous with that of clematis and one comes to look for something striking every year at Chelsea time.

Here are a few varieties to which we would draw attention, for the sake of their large, handsome blossoms, in some cases 9ins. to 10ins. across. The delicate pink Comtesse de Bouchard is probably the best of its colour, while Marie Boisselot easily takes

Digitized by Google

pride of place as the best white, with The Bride following on close behind. The best red is to be seen in the very free-flowering Mme. Edouard André, one of the parents of Crimson King, which is also on view Then there are the striking bi-coloured blossoms of the ever popular Nelly Moser and Marcel Moser, two varieties which will probably never be deposed from their position of popularity.

CARNATIONS

The carnation groups contributed not a little to the floral festival. Messrs. C. Engelmann of Saffron Walden have one of the most imposing collections of perpetual carnations exhibited for a number of years. The group contains about 8,000 perfect blooms of both new and old varieties. A magnificent pillar of Laddie occupies the centre of the stand. Near it Mrs. Hamilton Fellowes, Tarzan, Improved Ward and Mary Allwood make striking splashes of colour. Nero, a light purple pink, heavily stippled crimson, is one of their novelties, and some of the new varieties, not yet in commerce, are well worthy of a place among the leading kinds. Among the latter are Katja, a slatey grey carnation with a fine sheen; Dorcas, a velvety crimson and one of the most strongly clove scented carnations ever raised; while Palette is a variety of unique colouring, being a yellow ground carnation flaked and splashed with orange, red and pink.

For general excellence in arrangement and method of displaying carnations, Messrs. Allwood Bros. of Hayward's Heath deserve every congratulation. This firm are showing carnations of all types, including many varieties of perpetuals, border carnations, perpetual border carnations and Allwoodii. All the carnations, with the exception of the perpetual-flowering type, are growing in small beds cut in grass banks, a method of arrangement which is wholly commendable. The exhibit is in a prominent position at one end of the first tent. In the centre splendid specimens of such varieties as Master Michael Stoop, a glowing cerise; Shot Silk, an Indian chestnut; Topsy and Spectrum. On either side are the beds of carnations. In these the perpetual border carnations, Sussex Ray, Sussex Flake and Sussex Tricolour, are outstanding, while two new pink varieties, Phœbe and Elizabeth, are beautiful additions to the list of charming Allwoodii type.

A collection of perpetual carnations is exhibited by Messrs. Stuart Low and Co. of Enfield. The form, quality and size of some of the varieties shown leaves nothing to be desired. Particularly good are a number of blooms of the deep crimson Sir Philip Sassoon. Mrs. Ives Improved, Arnos Grove, Lady Hindlip, Duchess of York, Sheila Greer, and Sybil, a 1926 novelty, are representative of the collection. Another group of this same class was staged by the firm of Messrs. Keith Luxford. Iona is perhaps their best salmon pink variety; Circe, a mauve striped with pink; Nigger, a very deep crimson; and Coral Glow, a pink variety with apricot shading, is also to be seen on this stand.

Border carnations are shown by several firms. Mr. James Douglas' border carnations are known to every carnation lover. Mr. Douglas brings from Bookham a fine collection of some of the best varieties. Their size and quality are indeed of a high standard of excellence. There are many varieties included in the exhibit too numerous to mention.

Messrs. Seymour and Anderson also exhibited border carnations. Lady Shackleton, a soft pink variety, is in perfect condition; Steerforth, Paladin and Highland Mary are all very noticeable. Mr. C. H. Herbert of Birmingham is exhibiting several novelties of his particular race of pinks. Some of the new varieties are even more beautiful in colouring than older kinds.

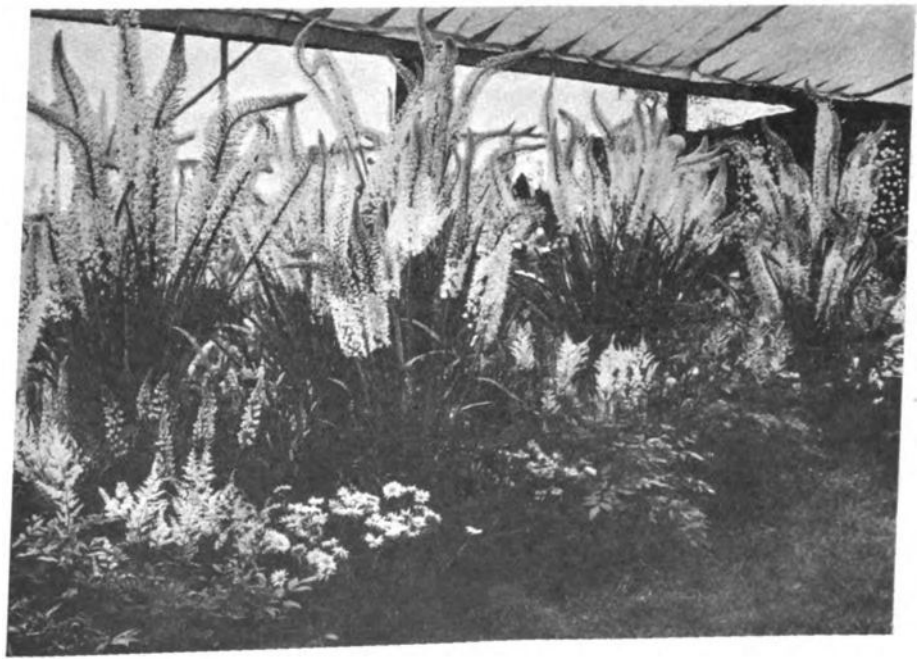
Messrs. Lowe and Gibson of Crawley staged an interesting group of border carnations. Several new varieties were noted. Mrs. Edmund Charrington, Joan Wardale and Myrtle Pettigrew, a variety of perfect form, should all become very popular. The executors of Sir William Cain have a unique exhibit which clearly shows that great skill and care in culture have been expended to produce such blooms as are seen here. Perpetual flowering carnations, perpetual malmaisons and Souvenir de la Malmaison growing in pots, are arranged in an imposing group. The malmaison Hon. Charlotte Knollys has surely never been seen in such perfection. A new perpetual-flowering carnation called Mrs. A. A. Vlasto is shown by Mr. J. C. Beck.

ROSES

The difficulties attendant on the postponement of the Show were probably felt more by the rose grower than the majority of the other exhibitors. From the show point of view timing the blooms is an all-important matter, and as the plants for Chelsea are all grown under glass, the difficulties may easily be imagined. But all the growers seem to have risen superior to the drawback, and there are many beautiful exhibits of roses to be seen in the tents.

For the most part the growers are showing the growing plants in pots, and they have arranged them with great skill and taste, making beautiful exhibits. At the Embankment end of the first large marquee Mr. Elisha Hicks has a most charming group

ROSES OF ALL TYPES ARE IN MESSRS. CUTBUSH'S GROUP.



GIGANTIC SPIKES OF EREMURI ARE SHOWN BY MESSRS. ARTINDALE.

Digitized by Google

of pot roses. Tall pillars and weeping standards of Lady Godiva, Evangeline, Minnehaha and other free-flowering varieties rise above dwarfer masses of America, Mrs. Henry Stevens, Blossom (a lovely pink variety), Margaret Horton and J. G. Glassford of the hybrid tea varieties, while the dwarf polyanthas are well represented by La Reine Elizabeth with masses of bright crimson flowers.

A similar position in the other large marquee is also admirably filled by Messrs. Chaplin Brothers, who have many splendidly grown plants of Chatillon Rambler, Excelsa, Lady Gay, Hiawatha and White Dorothy Perkins festooned with flowers. Near the front there are circular groups of La Reine Elizabeth and L'Ideal, two splendid dwarf polyanthas of bright colouring. Their hybrid tea varieties include Ophelia, Mrs. Henry Bowles, Mrs. Herbert Nash (a very dark crimson flower of delicious fragrance) and Maud (a well formed pink bloom).

A gracefully arranged group of roses with hydrangeas by Messrs. William Cutbush and Sons well fills a corner of the marquee. The roses are all of the useful, free-flowering polyantha type, and include the new Golden Salmon, of lovely colouring and great freedom. Locarno, another new variety, is of deep scarlet colour. The older varieties include La Reine Elizabeth, Mme. A. Kluis, Dorothy Perkins and Coral Cluster.

Towards the middle of the marquee Messrs. A. J. and C. Allen have an attractive group of pot roses, where they display Excelsa, Dorothy Perkins, Tausendschön, Paul's Scarlet Climber, Chatillon Rambler and Havering Rambler.

On the staging the Rev. J. H. Pemberton has a pretty little group of such free-flowering varieties as Topsie, Edith Cavell, Echo and Juliana; while the Devon Rosary Company are showing similar sorts.

Many excellent hybrid tea varieties are shown by Messrs. B. R. Cant and Sons in a large table space. The chief sorts are Sovereign, Lady Wakefield, Columbia, Padre and Rev. F. Page Roberts; while at the back they have profusely flowered plants of American Pillar, Hiawatha, Lady Godiva and Paul's Scarlet Climber.

In the front of his pretty group of roses Mr. George Prince has a small plant of the rare Rosa beridifolia Hardii, which is quite a small-growing species, bearing relatively large yellow flowers with rich crimson centres. He also shows a mass of the beautiful pink Lady Sylvia, Mme. Butterfly, Betty, Shot Silk and Coral Cluster.

Chiefly hybrid tea varieties of merit are shown by Messrs. F. Cant and Co., who have large vases of Capt. F. S. Harvey-Cant, Mrs. Henry Bowles, Comtesse de Cassagne, Chastity, Roselandia, William Kerdes and Mrs. F. S. Harvey-Cant.

Messrs. Ernest Paul and Co. have goodly vases of Golden Ophelia, Mme. Butterfly, Mrs. Henry Morse, Molly Sharman Crawford and other useful roses.

late being all the better for these plants. It is too early for the Bungei group, but the noble and bold E. robustus, the white E. himalaicus and the pink E. Elwesianus are here in all their glory. There are about eighteen large pots or vases with an average of a dozen spikes in each. The groundwork consists of lupins, spiræas, poppies, irises, and pyrethrums in great variety. An exhibit that ought to be seen by every visitor. Mr. A. Dawkins of Chelsea is represented by a small but showy group which contains a nice selection of Dutch irises, such as Blomard and

ONE OF MESSRS. HEWITT'S FAMOUS WREXHAM DELPHINIUMS.

Harkness and Sons, Bedale, Yorks, have pale blue lupins occupying a bold position at the back of their group, and a large vase of pink varieties in front. On either side can be seen the golden Trollius His Majesty, the tangerine poppies, a good batch of Viola cornuta purpurea and Viola Golden Wave, both charming rock garden subjects. Pyrethrums, Oriental poppies and heucheras complete the features of this display.

Messrs. B. Ladhams, Southampton, stage a group of hardy flowers characterised by their brilliance and variety. The double-flowered forget-me-not, Myosotis Orion, is sure to attract attention, and this remark applies to the vases of pyrethrum, verbascum and heucheras. The semi-climbing Solanum crispum can be seen, a good plant for covering old trees and buildings.

In the large and showy group so well set up by Messrs. Prichard, Christchurch, Hants, can be seen some beautiful lupins of various shades of pink, also blue and white. A few of the stately eremuri, Oriental poppies, the bright rose pink pyrethrum Hamlet, the dark P. Lady A. Harmsworth, P. Mrs. J. Linke (pink), and P. Snow White are all worthy of a place in every garden. Irises, anthericums, lilies, primulas and verbascums add their quota to an interesting display.

The lupins from Messrs. The Maytham Gardens, Rolvenden, Kent, are very effective: all are seedlings of Lupinus polyphyllus, and some will be seen again in different gardens, especially those with reddish and deep blue flowers.

A bold block of delphiniums occupies the centre of Messrs. Waterers' (of Twyford) exhibit. On each corner can be seen various lupins, the dark pink Delight being noteworthy. Grouplets of the pink Eremurus Elwesianus, the yellow Verbascum vernale, Anchusa Pride of Dover, and Lilium testaceum. Conspicuous is the pretty Verbascum densiflorum, the bold Iris magnificum, the dark I. Ambassador, and Lilium Szovitzianum together with various spiræas.

A small but choice lot of plants is staged by Mr. W. H. Walters, Colesborne Gardens, Cheltenham; the white form of Eremurus Elwesiana, and the white smilicina species being of interest. The coffin juniper is here on view also. Pæony arietiana alba, and different froms of cacti, all of value to the specialist in these subjects.

Messrs. Hewitt, Solihull, Birmingham, have staged upwards of twenty-five varieties of delphiniums, with a groundwork of ferns and a few primulas of the pulverulenta type, and acers. Among the finest varieties are Wembley, a strong grower, somewhat similar to the famous Millicent Blackmore. A lovely larkspur is Joybells, large, but graceful, the flowers of a deep rosy mauve shade. Another magnificent variety is Monarch of Wales, bright blue in colour with the inner petals reddish mauve. The Bishop is an improvement on Rev. E. Lascelles, and is sure to become a popular garden plant.

A cool and refreshing group of hardy ferns is put up by Mr. Amos Perry, Enfield, all in the rudest health. Here are also staged Eremuri, irises and strong primulas of the Red Hugh type and P. sikkimensis, not forgetting P. secundiflora, which is particularly well shown. Piptanthus nepalense, a golden yellow shrub, and Trollius Her Majesty are also represented.

In addition to flowering trees and shrubs, Messrs. Cheal of Crawley have a nice collection of herbaceous subjects. The yellow Thermopsis montana is here, together with spiræas, lupins, and a selection of primulas.

Messrs. Wilson and Agar, Crown Nurseries, Reading, have a selection of lupins, delphiniums, verbascums and irises.

The reports of other exhibits have unavoidably been held over until our next issue owing to limited space.

HARDY FLOWERS

Quite one of the best exhibits is put up by Messrs. Blackmore and Langdon, Bath. Here can be seen over two hundred spikes of finely grown delphiniums, in a variety of colours, all the stems being clothed with healthy foliage. The exquisite D. Millicent Blackmore is shown in quantity; it is pale blue and mauve, with a distinct black eye. Sir Douglas Haig is dark purple; Mrs. T. Baker, glorious sky blue; The Shah, distinct deep rosy lavender self; and George Cochrane, deep rosy purple. An excellent lot of flowers. The distinctive and noteworthy feature of Messrs. Artindale's, Sheffield, is the wonderful display of eremuri, the Show being a week

Celestial, also Gladiolus Peach Blossom and The Bride, Anemone Hollandia (a rich red flower) and various liliums.

Messrs. Storrie and Storrie, Glencarse, Scotland, have a nice selection of long-spurred aquilegias and a wonderful variety of their fine strain of polyanthus.

Mr. F. Gifford, Hornchurch, Essex, stage a pretty block of Pæony officinalis lobata. This is quite a good garden plant.

The Chalk Hill Nurseries, Reading, are represented by a fine block of Mimulus Chalk Hill Giant, Anchusa Pride of Dover and other named varieties, all similar to A. Opal. Polymonium Richardsoni, Aster alpinus, etc., can also be seen in this interesting group.

CORRESPONDENCE

ANCHUSA MYOSOTIDIFLORA.

SIR,—If your correspondent "T. W. B." wishes to grow this subject over 2ft. high instead of 1ft., and with such a mass of bloom that the foliage is almost entirely hidden, let him try it under a south wall, but in a position where it will not get too dry. It is growing all over the garden here, but succeeds nowhere so well as it does under the wall. Other plants are rubbish in comparison with this particular one.—A. H., *Ledbury*.

NEW AND BETTER GLADIOLI.

SIR,—I have been much interested in the articles of "C. H. A. S.," which have appeared in recent numbers of THE GARDEN; and as I think I can claim to have grown the spikes which illustrated the articles, I may be forgiven if I venture on a few remarks. No. 1, I think, represents Snow Glory and has the defect referred to, and for this reason I would suggest that White Glory might be tried in its place. This latter variety is not so ruffled as Snow Glory and the colouring is much the same. No. 2 is, perhaps, Mrs. John Hinkle, which was introduced with the usual flourish of trumpets, but as grown by me it did not come up to my expectations. It certainly had many flowers open at the same time, and I think that is all that could be said in its favour. Purple Glory is a good one and did well with me last year. It certainly attracted much attention when I showed it at the R.H.S. in the year after the war, and also again last year. Orange Glory is also a good flower when it does bloom, which, I am sorry to say, has not often been the case with me. It was such a disappointment that I wrote to an American correspondent for his opinions, and had a reply:

"Strange to say, your letter *re* Orange Glory came when Mr. Kunderd was here and he admitted that it was a shy bloomer, and was seriously thinking of taking it out of his catalogue."

I notice that this variety does not figure in his 1926 catalogue. "C. H. A. S." is quite right in stating it is a vigorous grower, but it does not produce flowers. If I could manage to get 50 per cent. to flower I would continue to grow it; but my average is much below 10 per cent.

By the way, should not the left-hand flower in the spike of Purple Glory be the one the writer wished to refer to?

Of those mentioned on pages 158 and 159 which I have grown, Catherine Coleman, Dr. F. E. Bennett, Mrs. F. C. Peters, W. H. Phipps and Richard Diener are, I think, the most outstanding. Majestic I grew some years ago and was much taken with the colour, but it was such a weak grower that I discarded it.—SMILAX.

THE ORANGE CORNER IN THE GARDEN.

SIR,—I should like to add the orange variety of Meconopsis cambrica to Mr. Cahen's list. It seeds itself most profusely in my garden and blooms from the end of April throughout the summer. In May it makes a brave show, combined with Cheiranthus Allionii. Some of the montbretias, also, are ideal for an orange corner, as is Geum Heldreichi.—R. G. H., *Bath*.

GLADIOLI FROM KENYA IN A CHESHIRE GARDEN.

SIR,—*A propos* of your recent number on gladioli, it may interest some of your readers to hear that in 1921-22 we brought back from Kenya some dozen bulbs of the wild gladiolus. They were turned up by the plough, on the high land, 8,700ft., and fifteen miles from the equator. Even those which have been left out each winter have flowered every year up to now. They are of the elegant light build, with the central hooded petal, and are all different shades of tomato to salmon colour.—J. A., *Cheshire*.

A WINTER GARDEN.

SIR,—May I correct "Chandlersford," on page 257. Anemone nemorosa Blue Bonnet is mentioned as being in flower while A. n. Alleni and A. n. Robinsoniana have not yet opened. The former is quite the latest to flower. A. n. Robinsoniana opens before A. n. Alleni. This latter is just past full flower and hardly a sign yet on A. n. Blue Bonnet. Possibly "Chandlersford" refers to A. n. cornubiensis, which flowers before all three.—ANEMONE.

TROPHY FOR PLANT BREEDERS.

SIR,—With reference to Mr. A. J. Macself's article under this heading in your issue of April 24th last, we have pleasure in forwarding to you an illustration of the trophy in question, which is being presented by us for progress in plant breeding at the Staffordshire and Midland Counties Show, which is being held at Burton-on-Trent on August 11th and 12th next. No doubt many of your readers will be interested to see this championship trophy.—MESSRS. ABOL, LIMITED.

THE CHALLENGE CUP
Presented by Messrs. Abol.

DAPHNE GENKWA.

SIR,—*A propos* of Mr. Bryce's note on the propagation of Daphne Genkwa. It seems a very difficult plant to grow and one seldom comes across it. Its beautiful colour ought to urge people to at least give it a trial. It is in full bloom here in a sheltered somewhat shady spot close to a big Scots pine. It has been in flower for over a month and not one of the plants seemed to mind 12 degrees of frost four weeks ago which did so much damage locally. I suppose one of the secrets of growing daphnes is to leave them alone. They don't like shifting in any shape or form.—G. H. DALRYMPLE, *Bartley, nr. Southampton*.

ANOTHER "COMING FLOWER."

SIR,—In a recent issue of THE GARDEN your Editorial referred to the gladiolus as "a coming flower," and the admirable items of letterpress and illustration which followed must have helped to concentrate attention very markedly upon it. I have hitherto only grown gladioli incidentally, but I have just planted twenty groups of choice varieties and hope to experience something of the pleasure of specialising this year.

But this is by the way. My real purpose in writing is to call attention to *another* "coming flower," also a South African—namely the lachenalia, not yet too well known nor appreciated at anything like its full value by growers who possess a frostproof structure, either a cool house or a sheltered frame; it is a plant which grows upon one with a fascination which increases with familiarity; recent developments have greatly added to its variety and beauty, and though it has lost a great advocate by the passing away of the Rev. Joseph Jacob, whose patient and persistent work upon it is widely recognised, it is fortunate that he was not working quite alone, and that there are advances still being made in the evolution of new varieties of great vigour and exquisite charm.

I hope that presently some further notes may appear, but there is one point which is very important at the moment, namely, that now the flowering season is over, and as soon as the foliage shows signs of tiring, water should be withheld, the bulbs at this stage absorbing only the retreating moisture from the foliage; the best place for the pots for some time to come is on a top shelf in full sun, where the bulbs will have a thorough baking and ripening, and they may even remain in the dry soil until the time comes for shaking out and repotting later on. No plant is more susceptible to small errors of treatment or is more joyously responsive when its simple needs are understood and observed. The point I have mentioned is especially the one to be acted upon *now*.—W. D.

FLORAL NOMENCLATURE.

SIR,—In reply to Mr. Bailey, I much appreciate his suggestions. I had a "Chaffinch," but not being a good enough flower, it was discarded and the name is waiting for the right flower to come along. Golden Oriole is here. I like the Pipes of Pan. What sort of colour would Mr. Bailey suggest for this? I admit I prefer a descriptive name, but not Crimson King and Yellow Queen and similar names. Altogether naming is a very difficult job. Recently at the Royal Horticultural Society, Mr. Herbert Chapman had a delightful narcissus, very well named Silver Salver, an attractive name and sufficiently descriptive.—G. H. DALRYMPLE.

A DRY WINTER.

SIR,—To my great astonishment while reading the leading article of one of the daily papers I found that April, 1926, was stated to be one of the wettest Aprils for some years. On looking up previous records, I find that with the exception of 1912 and 1914, it is one of the driest. Thinking it may be of interest to readers of THE GARDEN, I have compiled the enclosed chart for the month of April from 1911 to 1926.

RAINFALL FOR THE MONTH OF APRIL FROM 1911 TO 1926.

LLANDUDNO METEOROLOGICAL STATION.

Year.	*Rainfall.*
April, 1911	1.470
,, 1912	.420
,, 1913	3.260
,, 1914	.047
,, 1915	2.310
,, 1916	1.571
,, 1917	1.587
,, 1918	1.059
,, 1919	1.969

EELWORM AND HOT-WATER TREATMENT

FOR many years the daffodil was grown with very little trouble—provided one had a decent soil to grow it in—and its enemies were almost nil. Then all at once there was a rumour of a new disease doing much damage. I remember at one of the R.H.S. meetings talking to some growers and asking them about this new disease. They said you will soon know about it when you get it, and sure enough I did! The matter was taken up by the R.H.S. and one of their senior students was deputed thoroughly to work out the question, (1) as to what the disease was, and (2) to find a cure for it, if possible. The man chosen for the work was the late Mr. Ramsbottom, who made a most thorough investigation, and in the end found a cure. No man has done a more valuable work for horticulture, and all who knew him have a great respect for his work, and mourn his loss. Fairly early in his research Ramsbottom found that the cause of the trouble was not a fungus, but an eelworm (Tylenchus devastatrix). This creature, which is very small and can only be detected by the aid of a microscope, attacks the bulb near the neck, where the skin is most tender; it then works its way between the scales of the bulb and soon causes decay. These creatures multiply at an amazing rate, and very soon destroy a bulb.

Hot-Water Treatment.—This consists in immersing the bulbs in water at 110° F., for two hours for small bulbs, and three hours for large bulbs. Care should be taken to reckon the time from when the thermometer reaches the 110° mark, and not from when the bulbs are put into the water. The fact of putting a large number of bulbs into the sterilising tank will cause a considerable drop in the temperature of the water, which should only be raised again slowly or damage may be done. We now have very good outfits for the hot-water treatment: Hearson's for amateurs, and Barford and Perkins' for trade purposes. These have wonderful regulating arrangements which ensure a perfectly steady heat. I started "boiling," as we term it, before these things were brought out, and was content with an arrangement of a small saddle boiler, a square water tank, with a wood and wire cage to fit into tank. The cage is filled with bulbs (about 3,000 is a load), hoisted by a pulley and dropped into the tank, the water being about 110°. The temperature will drop some 10° and must be gradually again brought up to 110° by regulating the draught of the boiler. It will be found that with a simple apparatus such as described the water at the top of the tank will be many degrees hotter than that at the bottom. We overcome this difficulty by stirring the water with a stick. I do not recommend such an outfit, for it takes a lot of watching and overlooking; it would be far better now the improved boilers are on the market to invest in one. On the other hand, these things are a heavy expense for the ordinary amateur and he might well fight shy of them. I believe that, with great care and attention, the Fowler Lee bottling outfit might be used for small lots of bulbs, in fact I know it could, for I made my first effort with my wife's outfit! I would warn the intending bulb "boiler," to be very careful not to let the water get above 112°, even for a short time. Have some cold water handy and dash some in at once if the thermometer gets above 110°. It is, of course, necessary to sort the bulbs into sizes, so that those for a three-hour immersion may be done together, and those for a two-hour bath in another batch. After treatment the bulbs should be turned out into trays and sorted over, all which are very soft may be thrown away, the good bulbs should be left in the trays in the open for some days to let the wind dry them. Never put them into a closed building until they are dry, in fact, daffodil bulbs are far better if kept in an open shed, with roof to run off the rain, until they are dry; if stored in a closed building before they are dry, roots are apt to be formed, and if these are damaged by the hot water, the odds are against fresh roots being produced. The best time to treat the diseased bulbs is about middle of August; if done much earlier or later the results will not be so satisfactory.

Now a few words as to the effects of hot water on the bulb and on the flowers. If the temperature has been kept at its proper level, no harm will accrue to the majority of daffodils, but I have found certain varieties which hate the treatment. Frank Miles is one which very much objects to a hot bath; one year I treated a batch and hardly a bulb grew, but many of them grew after a year's rest. Two years ago I had a very bad bit of luck: out of all the thousands of bulbs treated, only four stocks seemed to suffer, and all these were the very choicest things, ranging in price from 25s. to £35 per bulb. However, I am glad to say that all have now recovered. In the great majority of cases "boiling" will not injure next year's bloom. I have cut hundreds of exhibition flowers from bulbs treated the previous summer. Ill effects are shown in different ways: "dud" blooms in the case of Bernardino and Gipsy Queen; poor undersized flowers on Mrs. Langtry and some others; and split trumpets in the case of trumpet daffodils—this, I think, always denotes a case of too much heat. Some few are benefited by hot-water. I have found King Alfred and two or three more early yellows bloom better after a hot bath.

It must be clearly understood that the hot-water treatment will not effect a 100 per cent. kill of eelworm; also, I think, that the "boiling" should be supplemented by digging out every unhealthy bulb seen in the beds during the growing season. The signs of eelworm in growing bulbs are: (1) retarded growth (one bulb just spearing through the soil, while the others have made some inches of growth); (2) deformed leaves and shortened or deformed flower stalks. When digging out suspected bulbs it is well to have a knife handy, and every now and again cut a bulb in two. If the section is quite white and free from any brown stain the bulb may be considered free from eelworm, but if the least sign of brown matter appears between the scales of the bulb it is pretty certain that eelworm is present and the destruction of the bulb is only a matter of time. A *very* important matter in dealing with this pest is to put the bulbs, after treatment, on to fresh soil. Experiment has proved that it takes three or four years to starve eelworm out of infected soil.

I may add that the Dutch have now nearly overcome the eelworm; in looking over many acres of daffodils in their farms last year I saw hardly any signs of the trouble. The same may be said of the more careful of our English growers, those who tackled the work in good time have now broken the back of it, but it has been a long fight.

Lowdham, Notts. J. DUNCAN PEARSON.

FRUIT AND VEGETABLES

ENDIVE.

LUNCHING with a friend interested in gardening, at a restaurant one hot day last summer, we were tempted to call for the "special" salad notified on the menu along with the cold viands with which we had been served. The bowl contained lettuce, cucumber, tomato, cress, and an addition which seemed to puzzle him by its white and pale green curly leaves. Turning to me he said, "What is this?"; and, leaning across the table, I whispered, "Don't you know endive?" His question struck me as being typical of so many who grow vegetables and who, for some reason hard to understand, leave out of their purview this valuable salad. Nothing is easier to grow than endive, provided seed is sown during May or early June in well dug and richly manured soil, or one in which has been worked vegetable refuse and road scrapings. Sowing in drills is the best method, thinning out to 15ins. or so apart, and blanching the plants when almost fully grown by covering with tubs, boxes or pots, to exclude the light. Endive is best served when given a sunny position, and must have abundance of water should the weather prove dry. The beginner with endive should not omit to blanch, as blanching improves its quality by taking away its bitterness and adds to its appearance also when served at table. Although it is getting late for sowing for a summer crop, opportunity can be taken to do so on south borders that are vacant, or in spare frames. The seed of Batavian varieties for winter use may also be put in during the next few weeks.—CLAREMONT.

OUTDOOR CUCUMBERS.

VERY good results can be obtained with the ridge varieties of cucumber in the open. A great deal depends upon the position chosen, and this should preferably be open to the south and sheltered by a fence or wall from the north and east. The cucumbers are best grown on hills and the preparation of these should be made ten days in advance of planting out. In each position open out a good sized hole in the ground and fill with stable manure. Then on this raise a mound formed of turfy loam and old manure in equal parts on which the plants are set. Allow about 4ft. between the hills. These preparations may seem to be elaborate, but the results justify the work. However, if the soil is naturally good, fair crops can be

THE AUTO-MOWER

THIS IS ONE OF THE SIMPLEST MOTOR LAWN MOWERS MANUFACTURED, AND IS BUILT ON SOUND ENGINEERING LINES THROUGHOUT.

SPECIFICATION :

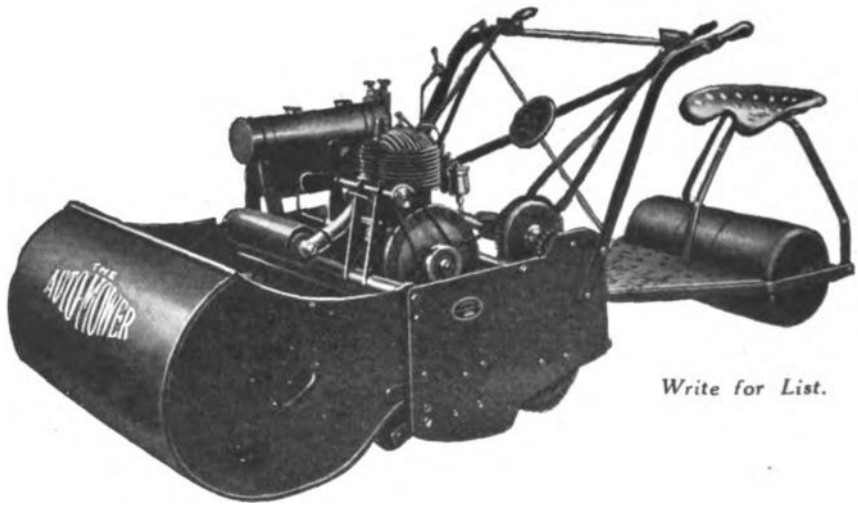
Ball Bearings throughout.

Steel Main Frame and Handles unbreakable.

Instantaneous Adjustment for depth of Cut—No Tools necessary.

24in. and 30in. Machines are fitted with two independent Clutches, also a Motor Car Type of Differential Gear which makes turning very easy.

ENGINES: All Models are fitted with a 4-stroke Engine with the exception of our 15-in. Model, which has an Engine of the 2-stroke type.



Write for List.

PRICES :

AUTO-MOWER

15in. £25 10 0 — 18in. £40 0 0

24in. £52 10 0 — 30in. £75 0 0

ROLLER SEATS EXTRA

18in. £4 10 0 — 24in. £6 0 0

30in. £7 10 0

Prices include free delivery to any Station or Town in Great Britain.

DEFERRED PAYMENTS CAN BE ARRANGED.

The Auto-Mower Engineering Co., Ltd., Norton St. Philip, near Bath.

BEAUTY and ART APPLIED to THE GARDEN, THE HOME AND PERSONAL ADORNMENT

Digitized by Google

grown on mounds which do not rest on a manure-filled pit. At the top of each hill scoop out a hollow and here set the plants one to each hill, at the end of May. Keep flower pots handy for covering the young cucumbers until they are well established and cold nights are things of the past. As soon as the plants begin to run freely between the hills the intervening space should be mulched with long manure. Carefully turn the stems back to allow the mulch to be placed well up to the plants. It is a very good plan to train the shoots out on all sides so as to expose each fully to light and air. To keep them in position used forked sticks pegged into the soil. The pegs serve the additional purpose of keeping the stems steady, so that they are not likely to be damaged by wind.

Watering, especially in hot, dry weather, is necessary. Fill up the depression around each plant at least once a day. As soon as the cucumbers start to bear, liquid manure is essential to help in the speedy development of the fruits. It is important to gather the fruits before they become large and seedy. Indeed, twice a week is not too often to go over the plants, removing all fruits that are ready for use. Any neglect in this direction will lead to the speedy exhaustion of the plants and cropping is soon at an end.—L. B.

GOOSEBERRY PESTS.

Methods of Destroying Foliage Maggots.

THE caterpillars of the magpie moth are small, but active in late autumn. During winter they hibernate in a torpid, quiescent state about the bushes or near it, to emerge in spring and attack the buds as soon as they show a tip of green. Growing more active as the weather improves, they are very destructive in April, May and June. They attain full size in the height of summer, pupate in dark, yellow-striped cases attached to the shrubs, and emerge as moths before the summer wanes.

The sawfly, on the other hand, lays her eggs on the leaves in early summer and the maggots which hatch out later on are greyish green, spotted black. Equally destructive, but faster to develop, they pupate in summer, emerge as flies a little later and produce a second brood in the same year. The last brood pupates in the ground below the bush during winter, to emerge as parent flies in late spring. The active caterpillars can only be fought successfully in one way, that is by poisoning the leaves—their food supply. This may be done by means of hellebore powder dusted or sprayed on the bushes, or, better still, with arsenate of lead or nicotine. None of these can be applied within a month of harvesting the berries. During this "off" season the plan is to hand-pick the pests, then quite large, and to destroy them. After the crop has been removed a strong wash may be applied at once. In winter sawflies can practically be eradicated by digging lime in around the bushes or, better still, lime containing 1lb. of crude naphthalene per 14lb.—at 1lb. to 2lb. per square yard. Magpie moths succumb at the same time to a good winter wash. Growers troubled with one or both pests should try the double-barrelled cure, a poison in summer and treatment in winter—a certain means of eradication.—CLYDESDALE.

BROCCOLI.

An Important Winter Vegetable.

I AM quite sure we do not, generally, pay sufficient attention to the broccoli crops in our gardens. Usually cultivators sow a few seeds of one or two varieties and the resultant plants turn-in in a group. Then there is waste because all the produce cannot be used as it should be. First, there should be a careful selection of varieties. Cultivators have their favourites, of course, but those who have not had much experience in growing this useful winter crop will be well satisfied if they select the following: For autumn use, Michaelmas White; for winter, Snow's Winter White; for early spring, Knight's Protecting and Leamington; for latest use, Cattell's Eclipse, Ledsham's Latest of All and June King. These varieties will afford a supply from early October until mid-June, when the earliest cauliflowers become available, thus avoiding a break in the supply all through the year.

Broccoli plants do not require a very rich soil because it is unwise to attempt to grow big plants with sappy stems. If a severe frost comes, the stems just below the leaves are the first to suffer. Ground on which peas and beans have been grown is suitable for the broccoli crop. If of poor quality rotted manure will do good, but usually it is only necessary to hoe and level the surface to darken it with soot and then put in the plants.—HANTS.

ASSISTING STRAWBERRY PLANTS.

ALMOST on the eve of gathering the crop, it is within the province of the cultivator to afford help to strawberry plants in beds and thereby ensure a more bountiful result. One cannot get away from the truth that the weather is a great factor, and makes all the difference between a good and an indifferent crop. If very wet during the period when berries are swelling, accompanied by cold, fruit is neither so plentiful because of it rotting, nor are the strawberries we gather so sweet. On the other hand, if it should happen that a dry time ensues during the next few weeks, with hot sun, it becomes a question of either fighting the adverse conditions by supplying the plants with nourishment, or leaving them to take their chance, and being satisfied with a meagre return for the year's labour. Having regard to the value of this welcome fruit, it is worth while using every endeavour to do all that is possible to ensure heavy baskets. Clean straw spread near the plants between the rows will keep the berries free from grit, and in a wet season prevents their detrimental contact with the soil. Mulchings of old manure, if not already applied, should be given, if possible, without delay. In the absence of a mulch, liquid manure in a weak state can be given once or twice a week after the fruit has set and before colouring takes place; but manure water ought not to be given as a substitute for pure water, which in abnormally dry seasons should be given with no unstinting hand each evening. Those who are unable to procure animal manures for diluting with water should obtain one of the highly concentrated artificials. It is the extra that we do for plants now that tells at gathering time.—W. F.

CARROT FLY.

A Gardener's Method of Treatment

THE success of the various preventive measures adopted depends very much upon the frequency with which they are applied. Though carrot fly and onion fly are distinctly different, the remedies prescribed for the one pest are, in general, suitable for coping with the other.

The aim being to disguise the smell of the crop, or to render the surface soil of the plot or bed more or less noxious to the fly or grub, a strong-smelling preparation like paraffin, sheep dip or soot and sulphate of ammonia is generally used. Paraffin emulsion, such as is used as a winter wash for fruit trees, is perhaps less suitable for treating carrot and onion plots than a simple mixture of sand and paraffin—from 1 pint to 1 quart of paraffin mixed with a bushel of sand and applied between the rows. Give three or four applications in the course of the early part of the season—from June to September. During very hot and dry weather a weekly spraying with paraffin may be necessary. Sheep dip is not nearly so effective.

For carrots the best preventive, immediately after hoeing, thinning and weeding, is:

(1) To firm the soil in the rows with the feet, pressing it against the carrots.

(2) Spray the rows with paraffin and water.

(3) Lay wads of newspaper folded to cover the whole space between the rows, and then cover these wads with small stones or coarse sand, or a mixture of both.

(4) Saturate this paper "mulch" with paraffin at the rate of 1 pint per 20ft. to 30ft. row.

(5) Sprinkle a little paraffin over the whole plot once a week in June, and every ten days or so thereafter.

(6) Give a good soaking of water in June if the soil is very dry after the "mulch" is applied. No more watering will be required. Little or no weeding will be necessary after treatment. The carrots will take care of themselves. They will make a vigorous growth. Onions have been treated similarly with success.—J. W.

CELERY.

The Need of Continued Care.

CELERY, unlike some few other vegetables that get along very well when given a start, tests the grower in point of skill and patience from the time when seed is sown under glass to beyond the earthing-up period. At present we are concerned with its final quarters, as in June plants should be removed to trenches already prepared and manured. Single rows can be better looked after than double, although by consent of custom the latter are more often seen. In planting out, 9ins. between one set of plants and the next should be the minimum, and, if at all dry, a good soaking of water should follow the operation. Being a moisture-loving plant, celery will benefit greatly by copious supplies of water whenever the ground is dry, and stimulants from time to time will help matters. Many amateur gardeners who grow celery are prone to leave the plants alone after planting out has been done, and overlook, sometimes until too late, the ravages of the celery fly. It is little use waiting until the fly has taken possession thinking one may deal with it, as it is well-nigh impossible to stop the spread of the mischief once the fly has taken up its quarters in the leaves. The better method is to make the foliage so distasteful to it that it will not become even a tenant. One of the greatest stand-bys of the celery grower is soot, and the plants should receive a dusting twice a week from the time they are in trenches, in season and out of season, whether we feel disposed for the job or not. Soot is the market grower's friend, and the amateur will find it a preventive of the scourge if persevered with. From a long experience in the growing of this vegetable I have found that if commenced with early in the season and used liberally every week a decoction made from quassia chips and diluted with water will keep the celery fly at bay. In any circumstances, and whatever plan we may adopt, prevention is always the best. There is no cure for the pest once it has found its way between the leaves, and if steps have not previously been taken to thwart it, whole rows of otherwise healthy plants may be ruined in a very few days.—W. LINDERS LEA.

THE GREENHOUSE

GREENHOUSE PLANTS

The Importance of Proper Re-arrangement.

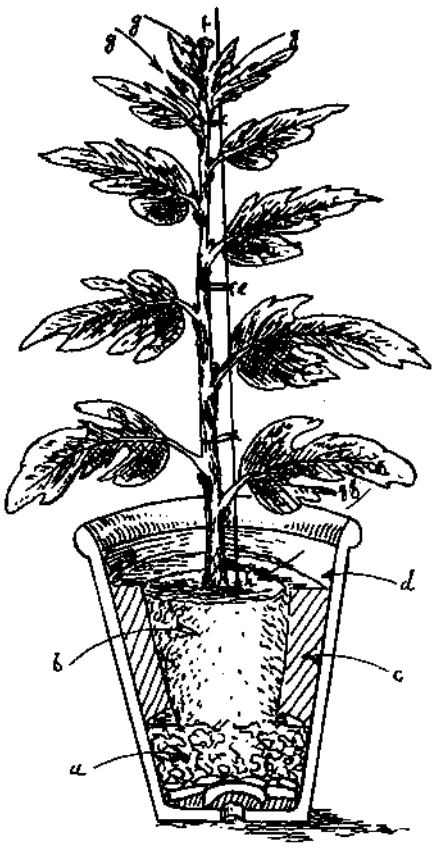
FORCED plants and those that have occupied the greenhouse during the winter and spring months, all except the permanent subjects, such as the climbers and a few kinds of pot plants, are nearly all useless for the furnishing of the structure during the summer months. It is at this season that the greenhouse gardener can, with safety, remove nearly all surplus stock to outside quarters or, at least, to cold frames. Others past future usefulness, and some of annual character, must be discarded altogether. Under the latter heading we have primulas, cinerarias, cyclamen, schizanthus, solanums, salvias and calceolarias. Of course, we must take into account those plants required for providing any new stock for next year. All such are carefully placed in cold frames and the old stems shortened so that fresh shoots will grow and provide suitable cuttings. Acacias, genistas, azaleas and similar kinds of plants should, certainly, be afforded cold frame room until about the middle or end of June. Failing a frame, provide a temporary shelter near a wall or fence. Before fresh batches of plants are arranged in the greenhouse, try to find time to clean it thoroughly, especially under the stages; and if possible, paint the top portions of shelves and stages, as the paint soon dries at this season and will preserve the wood against the constant applications of water during the summer months. Tiled, stone and cement paths often become quite green after the winter season. Where they are found to be in this condition, simply damp them and sprinkle dry lime over them freely; leave the lime on for a whole night, sprinkle more water on the following morning, then vigorously use a scrubbing brush before any lime is removed. When all is washed off it will be found that the floor looks bright and clean. To make wood paths last longer saturate them with clear water and then sprinkle on dust-dry cement. The structure will now be ready for the summer-time plants after all climbing plants in it have been cleaned and neatly, but not stiffly, tied up. Probably many readers will possess a few old zonal pelargoniums which they wish to retain. Few kinds of plants become more drawn-up during the winter-time than these, so it will be beneficial if leggy specimens are freely pruned into shape now and the prunings used as cuttings. The cut-back plants will soon grow and flower again. Young plants may need repotting, and all such should be arranged on shelves as any overcrowding will quickly spoil their shape, and this happens when such are mixed indiscriminately with older and larger specimens.

Tuberous begonias will, in themselves, furnish a greenhouse throughout the summer months, if need be; but most amateurs like to have variety. If the plants are not unduly shaded while they are small, they will do well throughout the summer, while in bloom, without undue shading if the structure is judiciously ventilated. Always arrange the plants by themselves and, to ensure as much space as possible for them on a small stage, place empty inverted flower-pots on the stage in odd places, to elevate some plants above others. This plan enables one to produce a pleasing effect, as it avoids formality.

Fuchsias are very charming plants and are suitable for all greenhouses, as hothouses can be judiciously shaded. Gesneras, gloxinias, campanulas, annuals and fine foliage plants should all have ample room; do not be tempted to overcrowd any of them. Provide a number of small ferns—Isolepis gracilis, Panicum variegatum and selaginella—in small pots to place as an edging to the groups on the stage and also to those arranged on the floor.—GEORGE GARNER.

THE FINAL POTTING OF CHRYSANTHEMUMS.

THIS work is not done on any given date, but it is usual to carry it out at the end of May and during the first half of June. Many plants are finally potted at the end of June and even in July. In the case of decorative varieties and those required for December and Christmas blooming, the later dates are sufficient if the young plants



have not been allowed to remain too long in the smaller pots and so become stunted. It is much better finally to pot late-flowering sorts early in June if they need the extra rooting space then, than to allow them to remain pot-bound for a month. Plants grown for exhibition would be partly ruined by such treatment; all are better for a shift to larger pots directly they need the repotting. The experienced cultivator knows quite well when such repotting should be done in the case of individual plants. Those less experienced should carefully turn out a few plants and examine the roots. The most forward ones—as regards root action—should be potted first, and so on until the whole batch of plants is dealt with. Two plants may be grown in a 10in. pot; one strong-growing plant in a 9in. pot, and one of naturally weaker growth in an 8in. The final potting of March-rooted plants should be in 7in. and 8in. pots, according to strength of variety. Compost: Fibrous loam, 2 parts; leaf-soil and old mortar rubble, 1 part; to each bushel add a 5in. potful of bonemeal, and sand if mortar rubble cannot be obtained. Pot firmly. *a*, compost; *b*, old ball of soil resting on the rough compost; *c*, general compost; *d*, space for water and surface dressing; *e*, tied to neat stake; *f*, bud causing break; *g*, *g*, *g*, side shoots to retain; *h*, stake placed in hole of former stake.—G. G.

BETTER CINERARIAS.

How Amateurs May Grow Large Plants.

IT is not really a difficult matter to grow fine specimens of cinerarias if there is a greenhouse and a garden frame available. I am now referring to the large-flowered section. One often sees plants possessing three or four leaves only and a head of blooms under average in size. It is much easier to grow bigger specimens of the star cinerarias, as, like the single-flowered chrysanthemums, the plants produce more roots, also stronger growth. Although the star-flowered cinerarias are popular, their popularity has not interfered with the demand for the large-flowered. The latter possess such beautiful flowers, large and well formed when grown from a good seed strain. Both large-flowered and star cinerarias are obtainable in a wide range of colours, including blues and purples of all shades, as well as pink and white varieties. Single large-flowered cinerarias in carmine ink are particularly attractive, while double-flowered types and a class of cross-bred varieties which are of intermediate habit between large-flowered and star cinerarias should also be tried. Seeds should be sown in April and June, then the resultant plants will bloom from autumn till May. The first batch should be the smaller of the two, as the spring-flowering plants will be the most perfect in every way. To obtain them sow seeds now. Three parts fill clean pots or pans with a mixture of old fibrous loam finely sifted, rotted leaf-soil and a small quantity of coarse sand—not any manure. Sow the seeds thinly on the newly watered surface; cover them lightly, place a square of glass on the pan and cover all with brown paper. Directly the seedlings appear gradually expose them to the full light, but not sun. Transplant in good time and pot off singly before the seedlings weaken. Repot several times, finally into 6in. and 7in. pots. Use rotted manure in these composts and summer the plants in cold frames facing north. House the plants in September and begin feeding when the flower-stem appears. Do not overcrowd the plants, nor subject them to a high temperature.—HANTS.

BOUVARDIAS.

BOUVARDIAS are such compact, attractive flowering shrubs for the greenhouse that one regrets owners of moderate sized houses do not make more use of them. Any plants that were cut back after flowering will now be furnished with young shoots which will serve as cuttings. These, if placed in a pan of peat, loam and coarse silver sand, within the warmth of a propagator or, failing that, on a shelf near the glass, will not be long in taking hold and should then be potted off in small pots, being finally transferred to 5in. pots. Their summer quarters should be on a bed of ashes in a cold frame where the sun can reach them, so as to aid in wood-ripening, an important factor in the case of bouvardias. From time to time weak liquid manure can be administered, and each plant should stand clear of its neighbour. During many weeks the lights need not be left on the frame; indeed, it will be an advantage to remove them so that the plants may get plenty of air. I fear that the popularity of chrysanthemums for indoor blooming has militated against the growing of compact, shrubby little plants like bouvardias, which bloom over a longer period and are of better service for table and window decoration—at any rate they are not cultivated to the same extent as formerly.—W. F.

MISCELLANEOUS

WEEDS ON LAWNS

How to Remove Them.

WHEN such weeds as daisies, dandelions, hawk weeds, plantains, etc., are to be seen on the lawn, it is proof that either bad turf was laid down or that the lawn has been neglected. An important point in connection with the management of all lawns is to keep a sharp look-out for weeds and never to allow a single one to remain. As a matter of fact, if a lawn is maintained in really good order, the growth of the grasses will be so close that the weed seedling stands a poor chance of development. However, it cannot be gainsaid that weeds will at times prove a nuisance on lawns, and steps must then be taken to eradicate them. In this connection the preparation known as lawn sand will prove most useful. This sand is thrown broadcast on the lawn in small quantities, and it has the power of destroying the large-leaved weeds without killing the grass. The operation must be repeated at intervals of a week or so until the weeds die out. If this is done in the early summer, the grass will soon extend over the bare patches where the weeds have been. Often it is worth while sowing grass seeds thickly in these positions and keeping them well watered to encourage a vigorous growth.

Where the weeds are not very numerous, these may be removed individually with an old knife. If the weeds are deeply rooted, their complete extirpation is not easy. In such cases it is well to cut away the crown of the weed, scooping out the top of the root as much as possible. Into the hollow thus formed put a pinch of salt, and there will then be no more trouble with that particular weed.—L. B.

WINDOW BOXES.

THERE is scope for a considerable display of taste in the filling of window boxes. No hard and fast rule need be followed. The main idea is to obtain a good show without overdoing it. Window boxes should not be overcrowded with plants. A few fine plants produce a better effect than a mass, and a simple arrangement of a few common flowers is far more beautiful than an elaborate mass of discordant hues. A very showy box can be had with begonias of different colours. Pelargoniums and ivy-leaved geraniums may appeal to some. Others might prefer fuchsias, calceolarias, scarlet geraniums, etc. As a set-off to a box of this kind, it could be edged with blue and white lobelia, finishing with a wreath of climbers—Tropæolum canariense or T. Lobbianum—round the sides of the window.

Window boxes look all the better if given a fresh coat of green paint. The flowers must, of course, be kept neat and trim. Withered leaves or faded blooms should be removed immediately.

Watering must be done regularly, but care must be taken not to make the soil in the boxes sodden.

A good soil to use in filling a window-box is a mixture of loam, 2 parts; river sand, 1 part; leaf-mould, peat and decayed turf, in about equal quantities to form 1 part. A little rotted manure may be added. Bone-meal and charcoal and soot are useful fertilisers. The various ingredients in the soil mixture or compost should be intimately mixed. The turf and fibrous material should be broken down, crushed and ground nearly to a powder. A sprinkling of fine sand on the top helps to prevent the surface soil from caking.

Watering is best done in the evening. A self-watering tip is to insert a cup or glass of water in the middle of the box, and to place the ends of two or three strands of wool in the water, the other ends being buried in the soil. The wool will convey the water from the vessel to the soil like a syphon, and so keep the plants moderately moist.—J. W.

GREEN FLY.

THIS fly attacks the tender tips of the shoots of roses, the young buds, the under sides of older leaves and the shoots growing from the harder stems and axils of the leaves there. Under glass the surest way to prevent attack and to destroy the aphides when found is to fumigate with Auto-shreds, sheets, or any good fumigating or vaporising compound, as sold by advertisers in THE GARDEN. It is always best to begin fumigating directly an odd fly can be seen, rather than later, when shoots are as badly infested as the one shown at *a*. Of course, in such case the end of the shoot is killed and the bloom lost. The shoot *b* is quite free, but delicate ones like it are soon spoiled. On buds, as shown at *c*, the fly

increases rapidly, soon appearing in the bud *d*, and later, unless checked, the aphides cover the young shoots that grow from the stem lower down, at *e e*. The letter *f* shows a green fly about natural size. In the open air it is best to use tobacco powder and to wash it off later with clear water, or to use a paraffin emulsion as sold ready mixed for dilution with water. Tobacco water is also good, and forcible syringing with clear water will dislodge many insects.—G. G.

THE GARDEN FRAME AND HOT-BED IN SUMMER.

IN winter and spring the garden frame is generally overcrowded with plants; but during the summer it is often allowed to remain empty—except for the weeds which soon grow in it. Unfortunately, such cases are not rare. Where there is a greenhouse or a conservatory to furnish during the winter months the garden frame will be found invaluable, as it may be used for the rearing of batches of primulas, cinerarias, cyclamen and calceolarias. The plants, being small in their early stages of growth, will not occupy much space. By autumn, when they are ready for removal to the greenhouse, it will be found that a single frameful will almost be sufficient to furnish a small greenhouse. While these kinds of plants are retained in the frame they must be fully exposed to a north, north-east or north-west light, while being shaded from direct sunshine. The frame on the mild hot-bed should contain cucumber plants. In an ordinary sized frame several dozens of cucumbers may be grown, and the only attention needed will be watering, syringing, ventilating and the stopping of the shoots; a few minutes' work each day. The lawn mowings placed to the sides of the bed will help to maintain the heat in it. If the frame is not required for the two purposes named, it may be utilised, early in July, for cuttings from the flower garden, as they strike readily in a sandy bed in a frame, cold or on a hot bed of manure.—HANTS.

GARDEN HOSE.

Hints as to its Management.

WITH the coming of summer weather the hose becomes an important part of the garden equipment. Most gardeners, even if the area of ground under cultivation is not large, should purchase a hose. Not only will a great deal of hard work be saved, but every part of the garden is rendered more productive. Probably the most durable type of hose is that in which the rubber is corrugated, for the ribbing makes the tubing resist wear to a remarkable degree. Some people are attracted by the hose with the spiral wire protection. This certainly guards the hose should anyone happen to tread on it. On the other hand, the wire tends to make the hose less flexible and not so easy to handle. Before buying the hose measure carefully how far it will be required to reach. Where there is no outside water the hose can usually be connected up with the tap over the scullery sink. It is well to have several types of nozzles so that sprays of varying degrees of fineness can be secured.

It is to be feared that many people who possess a hose find that the rubber is in a bad state after the long period of winter disuse. The rubber will probably be hard and brittle with a decided tendency to crack. Before attempting to use the hose it is an excellent plan to soak it in a tub of water for some hours. Then soak a large pad of cotton wool in glycerine and pass this along the whole length of the tubing. The hose may now be safely unrolled and there will be small risk of cracks. It may be pointed out that a garden hose will last almost indefinitely if, when out of use, it is stored in a tub of water. If this plan is not convenient, it is a good thing, before storing the hose, to rub it well with glycerine, which is most useful in keeping the rubber in good order.

A leaky hose is an abomination, and even the smallest hole should be treated without delay. A tiny crack can be sealed up in this way. Make a piece of stoutish wire red hot and then rub it well over the crack. With the melted rubber close the opening completely. Quite good results can be obtained by patching the hose in the same manner as is adopted with cycle tyres. It is important to remember that the affected part must be perfectly clean and dry, or the patch will not stick. Apply the solution to both sides of the patch to minimise the risk of curling. Place the patch on one side until the solution has started to set, and a very strong repair will be the result. Where some inches of the hose are in a very bad state the following is a good plan to adopt: Get a piece of brass tubing about 6ins. long; this must be of such a size that it will fit tightly into the hose. Now cut away the bad part altogether and link up the severed ends with the brass tube. If necessary, the hose may be bound firmly over the metal tubing with twine.—S. L. B.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

IN THE FLOWER GARDEN.

The time has arrived when all tender plants can safely be planted in the open ground. Pelargoniums, fuchsias, heliotrope, salvias, various annuals and the indispensable dahlia must all be set in their flowering quarters. If the beds are dry, well soak the soil with water a few hours before planting, and again after the plants are in position. May-flowering tulips can be lifted carefully, and the bulbs laid in some soil in the reserve garden until the foliage has ripened. When this happens, lift the bulbs and store them in a dry shed till October or early November. The herbaceous borders will need frequent attention, weeds must be kept down, and a certain amount of staking will be necessary. For most plants, neatly trimmed hazel or pea sticks are the most suitable, as they allow the growths to assume a more or less natural position. Watch for green fly on all roses, especially those that cover walls. Suckers ought to be removed before they make much headway.

Flowering Trees and Shrubs.—Many of these choice and showy denizens of our gardens are often allowed to grow more or less wild, and in consequence become overcrowded. At the present time a number of shrubs can be pruned, and they embrace such popular subjects as deutzias, philadelphus and lilacs. The latter should have the old flower trusses removed and one or two of the aged branches cut out if the bush is at all crowded. The shoots that have flowered are cut back to two basal buds. New growth should be encouraged in both deutzia and philadelphus, and, as a rule, there is quite a number of young shoots formed at this season. Pruning consists of cutting out the old flowering pieces to a strong, new growth, and these should be as near the base as possible. All trees and shrubs will benefit if the seed vessels are removed before they begin to tax the energies of the plants.

THE KITCHEN GARDEN.

Directly the seedlings are large enough, a start should be made in putting out all those vegetables known collectively as winter greens. For the moment vacant ground will be scarce, so the first to be planted must be the Brussels sprouts, and early cauliflowers, followed by broccoli, kales, savoys and purple sprouting. When the early potatoes are dug up, fill the space with kales, etc., until the requisite numbers are planted. Runner beans will need stakes, and peas ought to have supports before the haulm topples over. Summer spinach as it becomes unfit for the kitchen can be dug in to act as manure. Plant out ridge cucumbers and vegetable marrows. It is not advisable to cut asparagus after the first week in June unless it is exceptionally vigorous. Keep the beds free from weeds and afford liquid manure about once a fortnight, but the soil must be moist when it is applied.

AMONG THE FRUIT TREES.

Wall fruit trees must be examined periodically for insect pests, the young shoots of peaches and plums being susceptible to attacks of aphis. When these are present the trees should be thoroughly sprayed with a solution of insecticide, preferably in the evening, and washed with clean rain water the following morning. Much can be done at this season to reduce the pruning next winter, by disbudding or rubbing off a number of the young shoots. Such work should be done gradually until, finally, the growths are reduced so that the tree will be nicely furnished next year with new and fruiting wood. These remarks apply to peaches and nectarines, but plums, apricots and cherries may have their shoots pinched, excepting those required for extending the tree and filling space on the wall. Water the roots if the weather is dry, and thin fruits where crowded. Woolly aphis on apple trees should be painted with methylated spirit.

Chepstow. T. W. BRISCOE.

GREENHOUSE & CONSERVATORY.

Begonia manicata.—This fine winter-flowering begonia is very much neglected, which is surprising when one considers how beautiful and useful it is, for there are few plants that will not remain in perfect condition for over three months. Most cultivators make the mistake of keeping this begonia in too high a temperature at flowering time, when the colour is poor and washy and the display over in a few weeks. Where the night temperature does not fall below 45° Fahr., the colour is a deep pink and the display is maintained for several months. It should be propagated from cuttings towards the end of May, these rooting readily in a warm propagating case. Grown on into 6in. or 7in. pots, they make fine plants for the stages in their first year. Where large specimens are required the young plants should be grown on for a second year, repotting them into 8in. or 10in. pots. The variety aureo-maculata has blotched leaves, as the name indicates.

Winter-flowering Begonias, as represented by such fine single varieties as Optima, Mrs. Heal, Fascination, Exquisite, His Majesty and Orange King; also such double-flowered varieties as Scarlet Beauty, Sunrise, Miss Clibran, Clibran's Pink, Flambeau and Emily Clibran, should be propagated as cuttings are available. They should be secured 3ins. to 4ins., in length, and are best inserted singly in thumb pots in a light sandy compost. Placed in a warm propagating case with slight bottom heat, they quickly root, when they should be stood out on the stage well up to the roof glass. Some of the stronger growing varieties will require 6in. pots for the flowering size, while 5in. is quite large enough for the weaker growing sorts. In any case, over-potting must be avoided and careful watering practised at all times. They grow quite well in a compost that suits the ordinary tuberous-rooted begonias. Although subject to attacks of begonia mite, these can be prevented by the use of the sulphur vaporiser.

Euphorbia pulcherrima (Poinsettia), which is so popular for winter decoration in the warm greenhouse, may be propagated from now until the middle of June. The young shoots from plants that have been started into growth should be secured as cuttings when they are about 3ins. in length. Dip the cut ends in powdered charcoal to prevent excessive bleeding, and insert the cuttings singly in thumb pots and plunge in a warm propagating case. Care must be taken to prevent flagging, or else rooting will be slow and uncertain; where difficulty is experienced in rooting them from young shoots, the old stems should be cut into short lengths and used as cuttings, as they root readily. Plants raised in this way are not supposed to be so good, but I must say I have not noticed any marked difference in the ultimate result. In their younger stages they should be grown in a temperature of 60° Fahr., gradually accustoming them to cooler conditions until they will stand in a cool greenhouse, or even cold frames, the object being to keep them sturdy and short-jointed. Watering or feeding must be carefully attended to, or else the plants will soon lose their bottom leaves.

Brunfelsias are generally given stove treatment, whereas they flower freely and for a long period in an ordinary greenhouse. They can be propagated at this time by means of cuttings, which root readily in a warm propagating case. During their growing period they should be kept in a temperature of about 60° Fahr. When growth is completed they are best kept in a lower temperature and drier at the root. Generally they commence flowering during winter and early spring; but the flowering period depends largely on the temperature afforded them. For greenhouse work it is not wise to get them in flower too early, the beginning of April being soon enough. They produce their flowers over a long period, especially B. macrantha, which flowers freely in sixty-size pots. B. calycina is also excellent for pot work, as is B. eximia and B. Americana, a sweet-scented species.

Coleus thyrsoideus.—Where large specimens of this beautiful blue winter-flowering plant are required, cuttings should now be inserted in pots of light sandy soil. They root readily in a close case with slight bottom heat. Small plants for the stages can be propagated as late as August and September. For large specimens the young plants should be potted on as they require it until they are in 8in. or 10in. pots. They grow freely in any good potting compost, and during the summer months should be kept in a cool greenhouse. During autumn and winter they enjoy a temperature of 50° to 55° Fahr. This plant is by no means one of the easiest to grow successfully, and water at the root must be carefully afforded at all times.

Kew. J. COUTTS.

FOR NORTHERN GARDENS.

THE FRUIT GARDEN.

Close observation should be kept on the gooseberry and red currant plantations for the caterpillar of the gooseberry sawfly. The first small colonies may be destroyed by the application of hellebore powder. This can be used as a wet spray, and becomes more miscible if 1oz. of powder and 2oz. of flour are worked together in the form of dough, and then dissolved in 3 gallons of water. Hellebore loses its poisonous properties if exposed to the air for a time, yet it would not be wise to spray bushes from which the fruit is gathered green for cooking purposes.

From long experience I have every confidence in recommending for the purpose in view a spray of paraffin emulsion made as follows: Dissolve the required amount of soft soap—½oz. per gallon of spray—by adding successive small quantities of boiling water, stirring vigorously until a thick cream or curd is formed. To this add one wineglassful of paraffin to each gallon of water to make full strength. In the early season when leaves and shoots are tender, half the quantity of paraffin will be sufficient.

A severe attack of caterpillar is possibly best grappled with by spreading sheets of strong paper under the bushes and shaking the caterpillars on to the paper. This method may take a longer time, but is more satisfactory in the end.

A useful combination spray is formed by adding 1oz. of sulphide of potassium per 3 gallons of emulsion. This combination spray is very effective in the case of red spider on the bushes and as a preventive for use where American gooseberry mildew exists in a mild form. The above spray is most effective for use against the early attacks of aphis on "wall" trees. There is always a serious risk attached to the use of arsenate of lead as a spray in gardens in fear that some of it may be deposited on vegetables then in use.

Bedding down Strawberries should be done before the young fruits begin to weigh down the trusses. If obtainable, straw is the most suitable material for this purpose. Failing that, long grass, cut before the seed is ripe, answers well.

Black Currant bushes free from "big bug" will only require, meantime, to be constantly cultivated between the rows. Where big bud exists, continue spraying (dry) with a lime (1 part) and sulphur (2 parts) mixture.

THE FLOWER GARDEN.

While inspecting the rose beds a vigilant outlook should be kept for the rolled leaves sheltering the larvæ of the sawfly. Leaves adhering by a fine web will indicate the presence of the larvæ of various moths destructive to foliage and buds. Hand picking is the surest way of destroying these pests, owing to the difficulty of reaching them with a spray. Other pests, such as aphis and the larvæ of many sawflies and moths, which do not spin the leaves together, may be kept in check by regular spraying. For this, arsenate of lead is recommended and greatly used. I have found the home-made paraffin emulsion, liver of sulphur and soft soap mixtures most effective when applied regularly in graduated strengths. Begin with a weak solution in the early season, increasing the strength as the season advances, with consideration of the climatic conditions prevailing.

The presence of the sulphide in the mixture and its regular application is a necessity where rose rust, black spot and leaf scorch have existed the previous year, as a preventive to the recurrence of these in the present year. For mildew on roses the use of sulphide is more desirable than flowers of sulphur, as the latter is only effective in a fairly high temperature and in operation during the months preceding June and after July, the periods when mildew is most prevalent. Also, as mildew is generally worst on the under sides of the leaves, the wet spray is more likely to reach the affected parts.

Summer Bedding will occupy most of the time in the next day or two, and in preparation for it the various subjects to be used should have been well "hardened off."

When clearing out the spring bedding occupants retain, and strike in conveniently for later attention, sufficient plants to give the required stocks for cuttings of aubrietias and double arabis. Also retain first year seedlings and two year old plants of polyanthus for division and replanting.

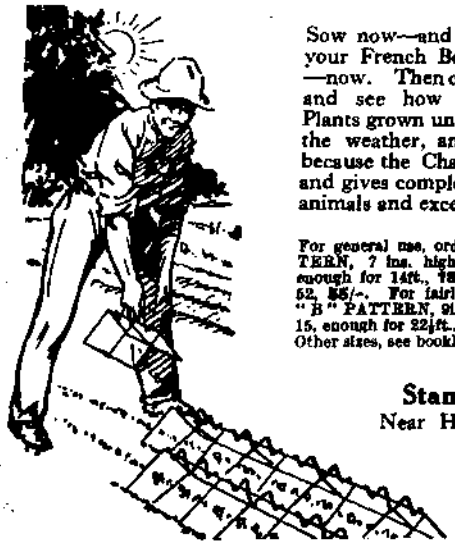
Chase Continuous Cloche

A Trap to catch the Sunbeams



Sow now—and use the Chase Continuous Cloche. Put in your French Beans, plant out your Tomatoes and Marrows—now. Then cover them with the Chase Continuous Cloche, and see how quickly they will grow big and sturdy. Plants grown under Chase Continuous Cloche thrive whatever the weather, and mature weeks earlier than in the open, because the Chase Continuous Cloche traps all the sunshine and gives complete protection against cold winds, frost, birds, animals and excessive rain.

For general use, order "A" PATTERN, 7 ins. high; box of 12 enough for 14ft., 18/-; 24, 35/-; 52, 55/-. For fairly large plants, "B" PATTERN, 9in. high; set of 15, enough for 22½ft., 35/- 50, 60/-. Other sizes, see booklet.

Free Booklet (explaining how the Chase Continuous Cloche saves labour, time and seeds, and ensures bigger, better crops) is gladly sent on request. Send a postcard *now* to Chase Continuous Cloche, Dept. 7, Chertsey, Surrey.

Stand 104 at Chelsea Show.
Near Hospital entrance, right-hand side.

Garden and Offices on Pound Pond, Stepgates, Chertsey.
Open 8 to 1, 2 to 5; Saturdays, 8 to 1

Carriage paid to nearest station in England and Wales; 1d. in the 1/- extra to stations in Scotland, Ireland, Isle of Man, Isle of Wight and Channel Islands. F.o.b. for colonial and foreign countries.

For success in your Garden USE

(*c*) **6** Cistus, in **6** older varieties, for **7/6**

All the above are bushy plants in 5-inch pots.

HILLIER & SONS of WINCHESTER

ANNUAL DATURAS

AMONG easily raised annual flowers for the greenhouse and conservatory few are more interesting than the daturas, or angels' trumpets, as they are called. Of these there are a number of varieties, wonderfully varied in form, colour, etc., considering they are so nearly related.

A collection from midsummer onwards gives a succession of large, often powerfully fragrant blooms, that, from the fact that they are so seldom seen, always arouse comment and admiration. The earlier the seeds are sown, in a temperature of 50 degrees, the better, for the more advanced in growth they are, naturally, the earlier they begin to flower. A light soil should be used and the seeds covered with about half an inch of this.

Water moderately and stand the pots near the boiler, or other warm place. Germination is fairly rapid as a rule, the seedlings pushing through with purplish stems and yellow, down-turned leaves that quickly spread and unfold. Directly they have formed one true leaf beyond the seed pair, prick them off into separate pots. A very rich soil is essential, fibrous loam, two parts to one of old sifted manure being good. Grow on in a steady temperature and, before they become pot-bound, shift again into a larger size.

Some forms branch naturally, others going ahead until the first flower buds form, then branching below that. It is a mistake to stop them with a view to encouraging earlier branching, as this delays the flowering.

Five or six-inch pots are large enough for good specimens and, once these are filled with roots, the plants should be fed generously with liquid manure. D. ceratocaula is a tall grower, reaching 3ft., with pink and white flowers. This is night-flowering and the large convolvulus-like blooms expand in the evening, filling the air with an exquisite fragrance. D. cornucopiæ, the horn of plenty datura, an illustration of which accompanies this article, is really lovely.

The flowers are similar in formation to the hose-in-hose polyanthus, one flower inside another. The buds are deep purple in colour and of huge size, expanding into great pale violet tubular flowers. I have flowered it outdoors in warm summers, but it succeeds best in the greenhouse.

ANTIRRHINUMS

IT'S only the fact that we grow and deliver especially good plants that we wish to advertise. The brightness, the long-flowering life, the wonderful adaptability of Antirrhinums (Snapdragons) are known to everyone. Although our plants are properly grown, transplanted, well rooted, hardened off, in all ways particularly good, as becomes a firm which reckon to do things well, the price is only

1/3 dozen. **8/6** 100.

Carriage paid on orders value 5/- and over, otherwise 9d. extra.

And these are the varieties and colours

Codsall Rose, delicate pink
Cottage Maid, pink, white throat
Crimson King, rich dark crimson
Dainty, gold and terra cotta pink
Electra, salmon orange, white throat
Dazzler, orange scarlet
Firefly, scarlet
Glow, orange apricot
Melrose, bright rose
Rose Queen, rose pink self
White Queen, pure white
Yellow King, rich yellow

Abol

The Standard Plant Wash

Abol Non-poisonous Insecticide is the "Best" sure-kill for Green and Black Fly, American Blight, etc. It is without an equal as a remedy for Mildew on Roses and other plants. It imparts health and vigour to the plant, and leaves the foliage beautifully clean and fresh.

Abol is perfectly safe to use on all flowers, fruits and vegetables, and will not harm the tenderest plant; has no unpleasant odour and will not damage paintwork.

Abol Non-poisonous Insecticide

Used in the Royal Gardens.

The Popular Insecticide "KATAKILLA"

THE attacks of insects on the crops are recorded many times in the classics, but no preventive measures appear to have been contemplated or applied. The insects either passed over the land, devouring the vegetation, or, in a few recorded instances, were stayed by some unknown cause reported to be miraculous. These appear to be the earliest records of insect destruction; how they were effected is a matter of conjecture, but there is little doubt that much was due to one of several causes, all of which work to-day in nature's scheme to keep each variety of life in its proper proportion. These controlling factors are either climatic, *i.e.*, strong winds, extremes of temperature; insectivorous birds and insects which feed on and destroy plant pests, *e.g.*, ladybird (coccinellidæ), lacewing flies (neuroptera), ichneumon flies, etc.; and lastly, the application either accidentally or intentionally of an insecticide.

The "Katakilla" Man usually associated with the marketing of the Insecticide.

The fact that certain mineral and vegetable substances have a destructive action on insect life has been recognised for centuries, and many of the principal insecticides were known to the ancients.

To the last three generations, however, has been left the development of the application of these insecticides.

ESSENTIALS FOR AN INSECTICIDE.

In order that an insecticide may exercise its full force on insect life, it must be applied in such a form that it is brought into intimate contact with each and every insect present. It must be applied in such a proportion that each insect obtains a fatal dose, and yet the insecticide is not wasted. In liquid insecticides, and those to be used as sprays, the first of these conditions is brought about by some spreading or water-softening agent which makes the spray fluid spread evenly over the plant sprayed and also envelop the bodies of the insects. The question of quantity of insecticide to be applied can only be settled by experiment, but for economy it is essential that the dose should be limited.

Insecticides can be divided into two classes: those that kill by contact and those that kill by poisoning the insect's food and thus killing the insect. Both varieties are necessary, as many hard-bodied, leaf-eating insects are not affected by the former, whereas the soft-bodied sucking insects which live on the sap of the plants are unaffected by the latter.

The ideal insecticide should therefore possess the following qualifications:

Economical in application;

Easily miscible with water;

Harmless to plants and domestic animals;

Spread rapidly over the plants treated;

Be fatal in contact with soft-bodied insects and effective in destroying leaf-eating insects;

Finally, the insecticide must be in such a physical form that it can be sprayed on to the trees and plants with ease.

QUALITIES OF "KATAKILLA."

"Katakilla," called by its manufacturers the Perfect Insecticide, embodies these requirements. Katakilla is a non-poisonous powder, readily miscible with water to form a spray fluid which will destroy all soft-bodied insects on contact, and will prove fatal to hard-bodied leaf-eating insects, though its value against these latter insects depends on the thoroughness of the spraying. Provided it is thoroughly mixed with a little water to a consistency like cocoa before being applied to the bulk of water, Katakilla will form a good, even solution without sediment.

Katakilla contains a well balanced mixture of insecticide and spreading material in such proportions as to produce a good, wetting spray, *i.e.*, a thorough spread, with waters of average hardness, yet the quantity of insecticide present is just sufficient to destroy insects without undue expense.

Katakilla, being absolutely non-poisonous, is therefore quite harmless to man and to beast. Fruit or vegetables recently sprayed are perfectly safe for consumption within a few hours, although, of course, it is wise to rinse them first in order to wash off any slight flavour of the spray material. From a marketing point of view Katakilla surpasses all other insecticides. Being a powder, leakage is unknown.

The packages are just those required by the amateur or professional gardener. One envelope makes one bucket of wash (2½ gallons); in one small packet the amateur has sufficient for four buckets of wash which can be made up all together or individually at will. No awkward measuring or intricate calculation is required. One large carton makes 40–50 gallons of wash. "Katakilla" is hard to beat, and well merits its reputation of being the Perfect Insecticide. It is stocked by the leading seedsmen, nurserymen, ironmongers, as well as all the large London stores, in 2s. and 6s. cartons. Should difficulty be experienced in obtaining supplies, apply direct to the manufacturers, Cooper, McDougall and Robertson, Limited, Berkhamsted, Herts.

MANURES.

The most complete little book on the subject is "The Manual of Manures," by H. VENDELMANS, 4/5; by post, 4/9. Published at the Offices of "COUNTRY LIFE," LIMITED, 20, Tavistock Street, Covent Garden, W.C.2.

VOL. XC.—No. 2844. JUNE 5, 1926

WHICH are the SIX MOST POPULAR SWEET PEAS?

THE sweet pea, like the rose, is everyone's flower. Like the rose, the sweet pea is being improved year by year. New tones, new flowering qualities, larger and finer flowers appear every season. So much is this the case that the number of varieties is now so large that it is difficult for the amateur to pick and choose his selection from the many magnificent kinds now on the market. He is in difficulties when the order season approaches what to buy and what to leave out. This is a serious question, for the sweet pea is a plant easily grown in a small area, and perfection is oftener attained in the ordinary garden than with almost any other plant.

£50 IN PRIZES

We are frequently asked, "Which are the six most popular, and therefore the best, sweet peas?" Like in the case of the rose, we are unable to answer; there are so many to choose from. In 1924 we held a competition in the pages of THE GARDEN, in order to find out by popular vote which are the six most popular hybrid teas. The number of entries was so large and our readers were so obviously interested that the competition was a triumphant success, and undoubtedly helped many of our readers in their selection.

We are, therefore, holding a similar competition with sweet peas, which, we are sure, will be just as popular, if not more so. The judging is entirely automatic: that is, the variety of sweet pea that gains the greatest number of votes is placed first by the readers of THE GARDEN, the next in number of votes second, and so on. This makes an attractive competition.

The reader who gauges most closely the public's taste of the six most popular sweet peas wins the first prize of THIRTY POUNDS' WORTH of goods as listed by any advertiser in the columns of THE GARDEN. Think what can be bought with £30. You may fancy a small greenhouse, or a lawn mower, or prefer a collection of plants or a set of gardening tools or some garden ornament, or, again, apparatus which will keep your plants in the best of health. Everyone has an equal chance of winning something that they will value both for and in their garden.

PRIZES.

1st PRIZE.—Goods worth **£30** from any advertiser in the pages of THE GARDEN.

2nd PRIZE.—Goods worth **£10** from any advertiser in the pages of THE GARDEN.

3rd PRIZE.—Goods worth **£5** from any advertiser in the pages of THE GARDEN.

20 CONSOLATION PRIZES of **5s.** each from any advertiser in the pages of THE GARDEN.

RULES.

¶ A list of your choice of the six most popular sweet peas to be sent in in order of preference on the coupon to be found on page vi of this week's issue of THE GARDEN. *No alternative* varieties will be allowed in the one list, but readers may send in any number of lists, provided that they are written on the special coupon to be found in this and the following five issues of THE GARDEN.

¶ Coupons must reach this office not later than Saturday, July 17th (after which date no coupons will be accepted).

¶ The popular vote will be final, and no correspondence will be entered into over this competition.

¶ Envelopes must be marked *Competition* and addressed to THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C.2.

¶ The Editor will not be held responsible for letters missing in the post.

¶ The result will be announced in THE GARDEN in the issue of August 28th.

¶ The prizes are awarded to those whose list corresponds most closely to that arrived at by the popular vote.

¶ If two readers tie for the first place, the first and second prizes will be equally divided; if two for the second place, the second and third prizes will be equally divided.

¶ The Editor's decision on all points will be final.

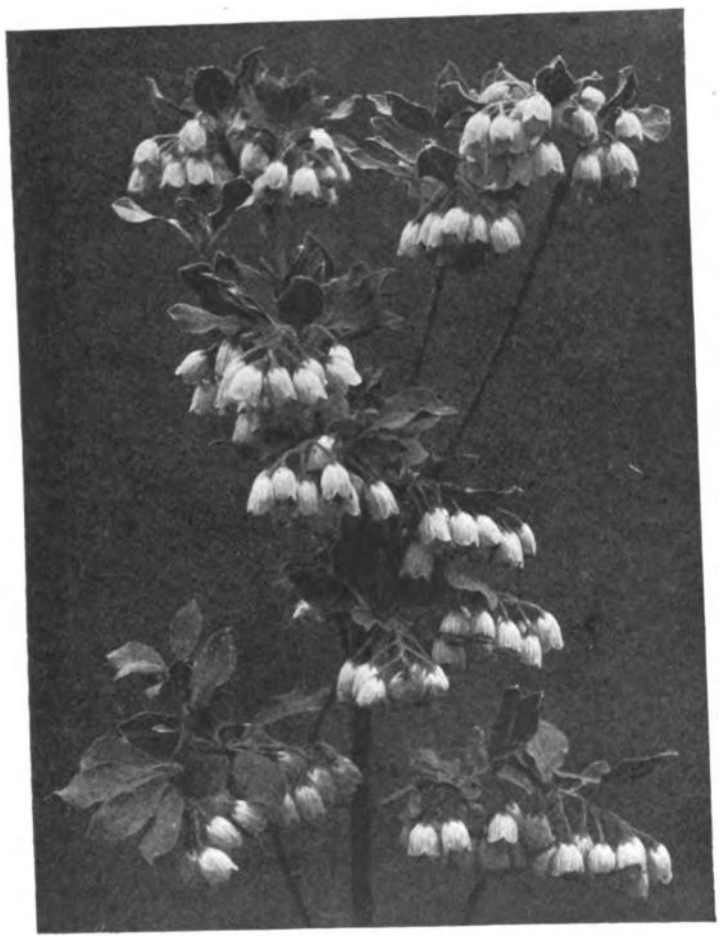
WORTHY PLANTS.—II.



ENKIANTHUS CAMPANULATUS.

THIS shrub is by no means a new plant, as it has been in cultivation in the British Isles since 1880. It has, however, been strangely neglected by the ordinary gardener. It was interesting, therefore, to see it shown on a number of stands at Chelsea, a sure sign that it is increasing in popularity. A catalogue of its merits is as follows: of quick and elegant growth, quite hardy, very pleasant when the creamy bells tinged and tipped with dull red are seen against the dull green of the leaves, very fine in autumn when the leaves turn a reddy-gold. Any soil that will grow rhododendrons or azaleas suits it and no special preparation is necessary provided that the drainage is good and the soil not too dry. It likes fairly full sun and an open exposure helps to retard its growth, for its only fault is its liability to being cut by late spring frosts. It is as well to plant it in groups not too close to plants with brilliant flowers, for it does not presume and so its charms are clouded when seen in proximity to brilliant tones. Many other species are said to exist, but there is a suspicion that they are all forms of either E. campanulatus or E. japonicus, a species with duller flowers, but of an even more brilliant colour in autumn.

NOW that Chelsea is over and done with, there is time to consider more leisurely what lessons are shown by this greatest of all Shows. First and foremost it has pointed out the fact that the popularity of gardening and horticulture is increasing steadily with measured force and not with a spurt that betokens a sudden boom and an evanescent popularity. More and more people are seen walking round the Show in order to learn, and not only to admire the beauty of the various exhibits. In fact, they are taking an interest in the cultivation as well as in the plants themselves.

Apart from the standard exhibits, that were better than ever this year—such as gardens formal and rock, alpines, herbaceous, roses, irises, clematis, orchids, tulips, fruit and vegetables—certain plants have come to the fore in surprising fashion; partly, no doubt, because the vagaries of the weather have suited them, but also because the demand is making for an increasing supply. One or two instances are easily noted. No one has ever seen such a display of Eremuri before. The gigantic, yet graceful spikes were to be seen on several stands and certainly these exhibits of a noble plant will do much to increase its popularity. Two other genera undoubtedly stand out in the same way, primulas and meconopsis. There are so many forms and varieties of the former now in cultivation that there are sufficient to gratify every taste, whether it prefers the old-fashioned polyanthus or the latest finds of Kingdon Ward or Forrest, such as the giant Florindæ and the graceful white chionantha. Unfortunately, meconopsis are bad travellers, which is perhaps one of the reasons for their unpopularity as a show plant, but that they were to be seen on a few stands proves that their popularity is increasing and that gardeners are becoming less terrified of them. Other examples could be given were there space. However, Chelsea shows that gardeners and owners of gardens are enlarging their collections by including plants that a year or two ago were grown by a few that could be named on one's fingers.

IT is pleasant to see that the special artists' tent at Chelsea has been so much appreciated and was so successful. The art of flower painting is an old one, as old as the growing of flowers itself. For the past few years it has suffered a decline which it is hoped that the innovation of a special artists' tent at Chelsea will help to remove. The paintings and drawings as shown by such artists as Miss Eva Savory, Miss Edith Fisher, Miss Nellie Blacklock, Mrs. Grace Carver and Miss Mary Elwes were excellent as works of decorative value and as impressions of the flowers depicted. It is a pity, however, that no one with something of the botanical in their artistic make-up has appeared on the scene. We lack a Redouté or an artist such as painted the illustrations for the "Flora Græcæ," "Flora Antilles," Wallich's "Plantæ Asiaticæ Rariores" and other monumental works of the past. In the case of garden design Mr. Percy S. Cane showed excellent photographs of gardens he had designed and a water-colour of a charming town garden, a restful scene of blues and greys. Other designs of note were shown by Miss Brenda Colvin.

IN our Correspondence columns will be found a letter from Colonel Cuthbert James, M.P., advocating that a law should be passed for the preservation of our wild flowers something after the manner of the Wild Birds' Protection Act. There is no doubt that some such act would go a long way in eliminating much wanton, or, at least, unnecessary damage to our wild flora. It has certainly been successful in the case of birds and there is no reason why it should not be equally so with plants. Colonel James lays particular stress on the relentless process of extirpation of the commoner flowers, whereas the loss of the rarer plants is even more serious, since their destruction is usually brought about by people who have some knowledge and should therefore know better. It is to be hoped, in any case, that the Council of the R.H.S. bestir themselves and see that this excellent suggestion of our correspondent comes to something. There is no authority that is conversant with the true state of affairs about our wild flowers and wields so much power owing to its enormous and growing membership. Meanwhile we should welcome constructive suggestions from our readers, many of whom have this matter at heart and are willing to do something towards saving our wild flora whether rare or common.

AMONG THE ARTICLES IN OUR NEXT ISSUE WILL BE:

NATIVE PLANTS IN OUR GARDENS—II, by Dr. R. Lloyd Praeger.

RED-HOT POKERS FOR THE AUTUMN GARDEN, by W. Fowkes.

Digitized by Google

SOME TIBETAN PRIMULAS

BY F. KINGDON WARD.

Many of the primulas described by the author in this article were on view in one or two exhibits at Chelsea last week, and the descriptions and history of these new introductions to our gardens may prove of interest after the plants have been seen in flower in this country.

IN addition to the Chinese and Himalayan primulas found in eastern Tibet, there are also a number of endemic species. Some of these, such as P. Florindæ, P. Waltoni and P. falcifolia, have already been dealt with. The majority, however, occur in the section Auriculata, which has few representatives in the Himalayas or in China. We found five species, the most interesting being P. pygmæorum, P. tibetica (K.W. 5739), P. glabra in two varieties (K.W. 5703), and P. Walshii (K.W. 5802), none of which occurs outside Tibet proper.

P. pygmæorum is a minute plant with a giant flower, bright rose, nestling among the spathulate leaves. It grows on grassy hummocks in moss, or on alpine grass slopes on the plateau at 14,000ft. We found it in flower in April, and did not meet with it again; but I got a little of the previous year's seed. Despite its bright, starry leaves, a welcome sight spangling the dead lawns of high Asia so early in the year, P. pygmæorum is small even for the rock garden.

P. glabra is another tiny alpine from turfy slopes on the rhododendron moorland. It grows half an inch high, with a spherical head of minute pink flowers. A variety with violet flowers grows on cliffs in the region of perpetual precipitation.

P. Walshii is not much bigger. It has rosy pink flowers which open in May, and grows on alpine turf slopes.

The best of the bunch is the little P. tibetica, a bog plant with carmine flowers, which is quite common. The alpine bogs and lower meads from 11,000 to nearly 14,000 ft. are absolutely inflamed with it throughout July. It sometimes attains a height of 6ins., and if grown in sufficient mass will be a useful addition to the bog garden, for though in cultivation, it is rare.

The Petiolaris section is well represented in the forested parts of Tibet, with four species. P. Whitei and P. irregularis are well known Sikkim plants. P. chionota (K.W. 5868) is a new species with bright yellow flowers. It grows in rocky pools and on alpine mud slides on the very wettest mountain ranges at 12,000ft. to 13,000ft., flowering towards the end of June.

Much more abundant is P. Roylei, a plant of the woodland glades with cherry red flowers. Most of the Petiolaris primulas are sylvan, and we have only one of them—P. Winteri—in cultivation, and that not happy; the reason being that we never grow our woodland primulas in woods, though our own beautiful wild primrose is sometimes—not always—permitted to remain there. We have unreasonably convinced ourselves that the only place in which to grow primulas is the rock garden. Shade may, indeed, be provided in the rock garden; but, apart from that, the conditions under trees are entirely opposed to those met with on rocks, and one need only compare the voluptuous root system of a woodland plant with the weedy spider's-web roots of a rock plant to see this. To begin with, woodland soil, both in texture and chemical properties, is quite different from rock soil, and it is *always* moist, not merely at stated intervals when the watering pot is handy.

P. Winteri and P. Roylei ought both to be grown in the wood; the latter, flowering among the bluebells in June, would make a harmonious coalition.

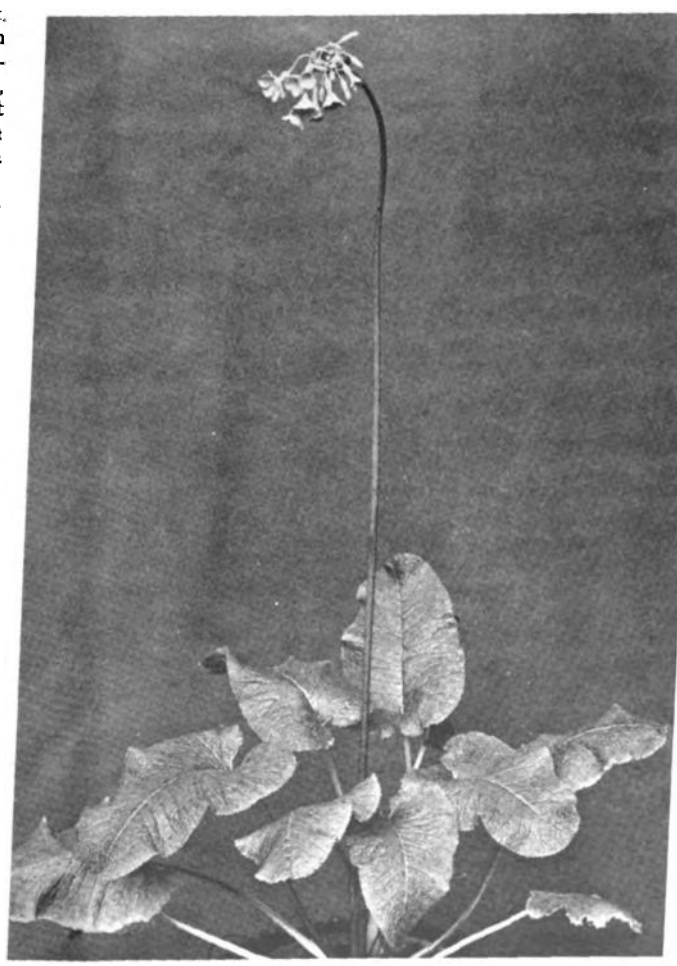
Section Geranioides, which has both Chinese and Himalayan representatives, furnished one good plant, and that a new species P. latisecta (K.W. 5819). It covers steep, loamy banks under trees, preferring heavy shade and a well drained soil. Seed was not collected till January—it flowers in June—but has germinated well, and the plant should be useful for woodland, being distinct both in flower and foliage.

Section Rotundifolia is confined to the Himalaya and Tibet, and includes rock plants from high elevations. We found two species, of which I need only mention P. Baileyana (K.W. 5985).

Now, it is a fact that, in this country, rock primulas, which generally means alpine primulas, rarely do well, the reason being that they are accustomed to sleep soundly for at least five months in the year. When the snow melts in May or June, having reserved their strength and vigour, up they come with a rush; but in England they are too apt to dissipate their strength and damage their health with several false starts. Thus they fall easy victims to late frosts and cold damp.

There is not a single popular hardy rotundifolia primula in cultivation to-day, though they are among the most charming rock primulas known. The fact is, they must be grown not only in the rock garden, but on rocks. Planted in gritty soil, where moisture cannot collect and stagnate, in the crevices of a rock wall facing south—for sun never hurts them—they would have a chance.

I mention this because P. Baileyana, now that it has germinated so freely, is a plant well worth persevering with. The curious shape of the leaves on their long flexible petioles, which allow the blade to twitch over, partly exposing the bright silver white under surface, and the neat heads of bright violet flowers are quite unusual. But a single specimen plant is not much use. What we require of our rock gardens is not a museum, but an impressionistic effect of life and colour and dainty freshness; and this is *only* to be achieved by judicious massing and blending, *not* by scattering plants like currants over a rock cake. This is where we can triumph over nature, for we can arrange and select our plants as Dame Nature would like. For instance, a



P. FLORINDÆ, THE GIANT COWSLIP PRIMULA OF THE SIKKIMENSIS GROUP.

This species was awarded a first-class certificate at Chelsea.

Digitized by Google

mass of P. Baileyana in a rocky nook, or bands of it along a wall, would produce a charming effect; but we never saw it growing so in Tibet—there was too much competition.

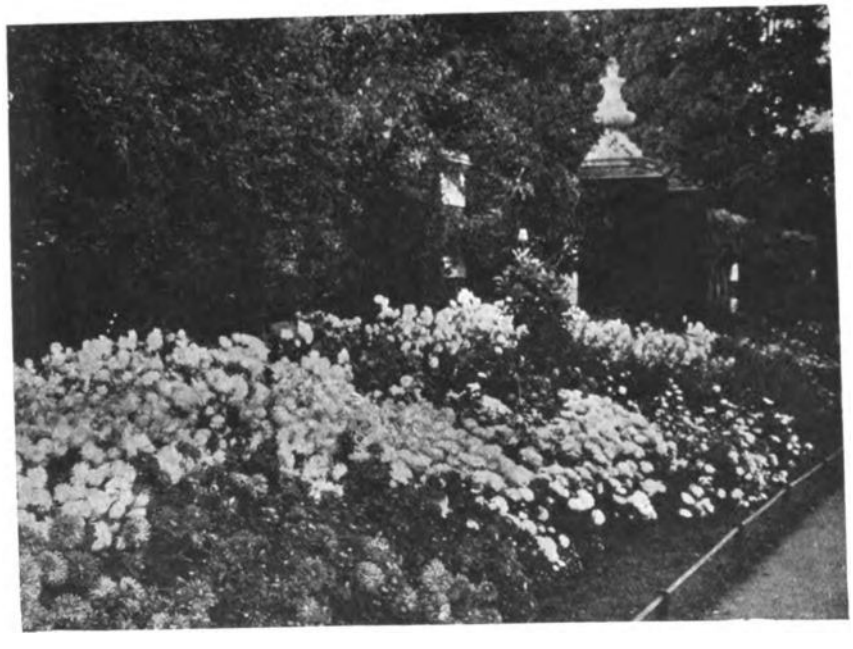
In a previous article I stated that P. chungensis was the only "Candelabra" primula met with. But if the Chinese P. serratifolia is classed as a "Candelabra," which it is at present, then the golden primula, P. Morsheadiana (K.W. 5858) must also be so classed. I only hesitate for this reason. There are two good diagnostic characters for the candelabra section, (i) Habit, (ii) Capsule. The latter is no doubt the more important, and P. serratifolia has got it, but the former it has not got, neither has P. Morsheadiana, a new species from the home of P. falcifolia. P. Morsheadiana resembles P. serratifolia in size and appearance, but its flowers are of a uniform bright butter yellow, instead of bicolor—gamboge and lemon. It grows on grassy, not to say slimy, alpine slopes in clumps, favouring more sheltered situations than the daffodil primula, and like the latter it may flower either in spring or autumn. We found some fine winter clumps flowering bravely in the snow. The capsules of these two species are very similar, which is the reason why I cannot regard P. falcifolia as a true nivalid. The golden primula is not fragrant.

Lastly there is the dainty P. Cawdoriana (K.W. 5741), a new species of the section "Soldanelloides," which contains the lovely little Himalayan P. Reidii. Two striking features of P. Cawdoriana are the massing of the few flowers on one side of the head and the length of the deeply cleft corolla tube, which often exceeds an inch. The colour is violet.

The plant was found growing in masses on shaded rocks and banks in thin, well drained hungry micaceous soils, at 13,000ft. to 14,000ft., flowering in June and July. The seeds are germinating fairly well, and its strange appearance, with the long-tailed tubes streaming off the 6in. stems, would well repay a little trouble. There is nothing like it in cultivation.

EARLY-FLOWERING CHRYSANTHEMUMS

IN common with many other popular flowers, early-flowering chrysanthemums have been much improved during recent years. A large number of the newer introductions are undoubtedly acquisitions, but many of the older favourites are still indispensable. A really good collection of the standard kinds can be obtained for a modest initial outlay, and as most of these produce cuttings very readily, a large stock can be worked up in a few years. For those who wish to keep up to date with the later introductions the cost of these is not exacting, and there are practically no losses if reasonable care is exercised.



FOR COLOUR AND BEAUTY IN THE AUTUMN BORDER EARLY-FLOWERING CHRYSANTHEMUMS ARE HARD TO BEAT.

WHEN AND HOW TO PLANT.

Now that all danger of frost is past plants can be put into their permanent quarters as soon as possible. The earlier in the month that this is done the better, as the chrysanthemum likes a long period of growth. Thorough soil preparation is essential, and sufficient animal manure should be incorporated in the soil to ensure that there is no check in the steady development of the plant during the height of summer. The cause of many failures and an indifferent display of bloom can often be attributed to careless soil preparation. In addition to animal manure it is a good plan to work into the soil a liberal quantity of bone meal. If the plants are grown on a site that has been formerly used as a potato plot, soil conditions should be admirable, and the ground should not need such a heavy dressing of manure. Choose an open situation that receives a maximum amount of sunshine if possible. Where the plants are grown solely for garden display some attention should be paid to colour arrangement. By a judicious blending of the shades many pretty colour combinations can be obtained. If a warm effect is desired, the richer colours should predominate. Vivid shades of orange, terra-cotta, crimson or scarlet, or blends of these, will give bold masses of rich colour. Whites, creams, pale yellows and blush pinks will give cooler contrasts.

Allow the plants sufficient room to develop. The exact amount of space to allow between the plants will depend upon the garden room available. It is unwise to crowd chrysanthemums among tall-growing perennials that are liable to outgrow them and take possession of light and air. Firm planting is also essential, and it is a good plan to tie the plants to canes or stakes as soon as they are put out in the border. This reduces damage from winds to a minimum, and also keeps the plants in an erect position.

THE EARLIEST VARIETIES.

As a rule the earliest varieties to bloom are the "Polly" type. Polly is one of the oldest of the standard sorts. It is a deep orange with amber shading, and usually grows to a height of 1½ft. In southern and midland districts it can be had in bloom in August in a normal season; in the north it begins to flower towards the end of that month. Crimson Polly and Golden Polly are two "sports" from the older variety, with the same characteristics as the original of the type. Abercorn Beauty, another "sport," is a rich bronze with reflexing florets, and, like all the type, is both robust and free flowering. Florrie Wilkinson is a deep yellow "sport," and is regarded by many as the best of the Polly type.

I have usually found that Saracen, one of the newer introductions, comes into bloom towards the end of August, and its large blooms are a rich shade of deep amber with darker centres. With good culture this variety can be made to flower over a long period. The same early and continuous flowering habit can be attributed to Mary Houston, one of the best varieties from Tollcross. Mr. McAlpine has had this variety in flower with the earliest kinds and also exhibited it as late as November. It is best described as an improved Goacher's Crimson.

THE MASSE FAMILY.

Here we have a strong-growing and particularly free-flowering type that seems to succeed anywhere. One finds this type in almost every town and suburban garden where chrysanthemums are a speciality. Improved Masse is a large rosy lilac with a silvery reverse, and bears large double flowers that make excellent sprays. White Masse is not quite pure white, but it is an excellent light-coloured variety for sprays. Horace Martin and Elstob Yellow are two very good yellows

Digitized by Google

of this class, and Mrs. J. Mason is a fine shade of old rose. Rabbie Burns is an old favourite, having rosy cerise flowers and a free branching habit. George Bowness is crushed strawberry and is also a favourite of the Masse type. One of the best is John McAlpine, a splendid grower and very delicate and pleasing in colour, which is rosy pink shaded with apricot and yellow. This variety gives a very large number of cuttings.

THE GOACHER'S CRIMSON TYPE.

Goacher's Crimson needs no introduction to the reader. At its best it is a very desirable standard sort, and succeeds well in most localities. Golden Goacher is a golden bronze "sport" and Bronze Goacher is a deeper bronze. Mrs. J. Fielding also belongs to this class and bears rich chestnut bronze flowers of fine form.

THE PERRIER TYPE.

Another of the free-flowering and easily grown earlies. Mme. Cassimer Perrier, creamy white tinted with pink, is found in most gardens. Cream Perrier is a creamy white sport from it, and Mrs. A. Willis, another sport, is yellow shaded with red.

OTHER GOOD STANDARD VARIETIES.

Reine des Blancs and Roi des Blancs are two excellent early white varieties. I prefer the former. Nina Blick is another very fine old variety that cannot be omitted. It usually blooms early in September. Pluie de Argent is a fine white variety for garden display. It grows to a height of about 1ft., and well grown specimens are literally a mass of bloom. Alexander McAlpine is one of the very best of the earlies either for garden or home decoration. Its flowers are of good form and the colour, a rich golden orange, is particularly pleasant in artificial light. Crimson Diana and Golden Diana are two excellent varieties for the garden, having a neat habit and a very free-flowering character. Ena Thorpe, a large flesh pink, gives good sprays for cutting, and this variety is also fine when disbudded. Harry Thorpe, deep yellow with a fawn suffusion in the centre, is also a good variety for decorative purposes. The rich shade of Dick Barnes, burgundy crimson, is very attractive, and Harvester, a light bronze, is also a favourite for home decoration. Wembley is a splendid decorative variety of intense blood red colouring.

VARIETIES FOR EXHIBITION.

Some of the later flowering kinds, which can be lifted from the open and finished under glass if desired, will give fine exhibition blooms if disbudded. These include Blanche du Poitou, Primrose Poitou, Cranfordia, Cranfordia Supreme, Soliel d'Octobre, Bronze Soliel d'Octobre, Emperor, Armorel, Anthea, La Pactole, Yellow La Pactole and Belle Mauve. Jessie McAlpine, which comes practically pure white when finished under glass, is a fine exhibition variety when disbudded. Silver Queen, warm pink with a silvery reverse, comes as large as Cranfordia when disbudded, and this is undoubtedly a notable new variety.

A SELECTION OF SINGLE CHRYSANTHEMUMS.

The later introductions in singles are far in advance of the older sorts. Mr. Woolman has worked assiduously in the evolution of a better petalled flower, and his newer kinds are stronger in habit and the blooms are capable of resisting the wet. I have grown most of his recent novelties. From many good varieties I recommend the following half-dozen as being of outstanding merit: Papyrus, deep velvety crimson; Delice, bright pink; Doreen Woolman, golden orange; Morning Star, golden amber; Orange Girl, golden orange; and Shirley Terra Cotta, bright terra cotta. All these are very beautiful colours in lamplight. Mr. Woolman tells me that his new early-flowering varieties, which include Periscope, a single yellow, are regarded as the best set he has sent out.

HOW TO FEED THE PLANTS.

For a top-dressing use eight parts of sulphate of ammonia, six parts of superphosphate of lime and one part of sulphate of potash. As a stimulant use alternately a mixture of liquid manure made from cow dung and soot water, and one part nitrate of potash, two parts phosphate of potash to half a gallon of water. Use the liquid fertilisers in showery weather if possible.

NORMAN LAMBERT.

NOTES OF THE WEEK

IVY-LEAVED PELARGONIUMS.

AMONG pelargoniums the section known as the ivy-leaved, with their straggling, pendulous nature, is of particular value, as plants which were struck, maybe, only this spring soon respond to culture as to be serviceable for use in a variety of ways. They have always been favourites for furnishing hanging baskets and window boxes, and it is generally agreed that it is better to start with young plants for such purposes, rather than attempt to press into a confined space roots of older specimens. The present is a suitable time to get them into their intended quarters. If in baskets, care should be taken to line them with moss and press the compost well down about the roots. A very plain diet is all that is needed for ivy-leaved pelargoniums, and should consist of old loam and leaf-mould, with a little sharp sand added. For window boxes they are particularly effective, as they soon drape and festoon down the sill as to make quite a common receptacle very charming, owing to the prodigality of blossoms. Vases in the garden, as well as banksides on the approach to a house, may be adorned with them. Within recent years, too, I have noticed where summer bedding is undertaken, *e.g.*, on lawns, they are becoming more largely employed; and there is this to be said in their favour, at least, that they bloom continuously for some months. Where these pelargoniums are employed for indoor decoration, it will be found that a 5in. or 6in. pot is a convenient size, and any plants in need of removal should be potted forthwith. In the case of old plants which may have occupied the same pot for a number of years, it would be to their advantage to give them a change, even at this date, either by removing them to larger pots, or planting them out of doors in beds or borders. In turning them from their present pots, some of the old, worn-out soil should be removed, and if kept within the greenhouse for a time they speedily recuperate. So dealt with, one is more likely to obtain a better show of bloom than if left for the summer in compost that has long since lost its nature. I do not think that so much use is made in covering back walls of lean-to greenhouses as formerly, but for permanency there is much to be said in favour of ivy-leaved pelargoniums, especially where they are planted out in a border within the house. They grow very rapidly and, once established, are wonderfully profuse with their flowers. In thus quartering them, it is essential that plants should have the fullest advantage of light.

The following varieties are among the best double-flowered varieties: Beauty of Castlehill, deep rose pink; Mrs. W. H. Martin, mauve; Beauty of Jersey, reddish purple; H.M. the Queen, salmon; Mme. Crousse, pale rose; Jeanne d'Arc, white, veined lilac; Scarlet Mme. Crousse.—W. LINDERS LEA.

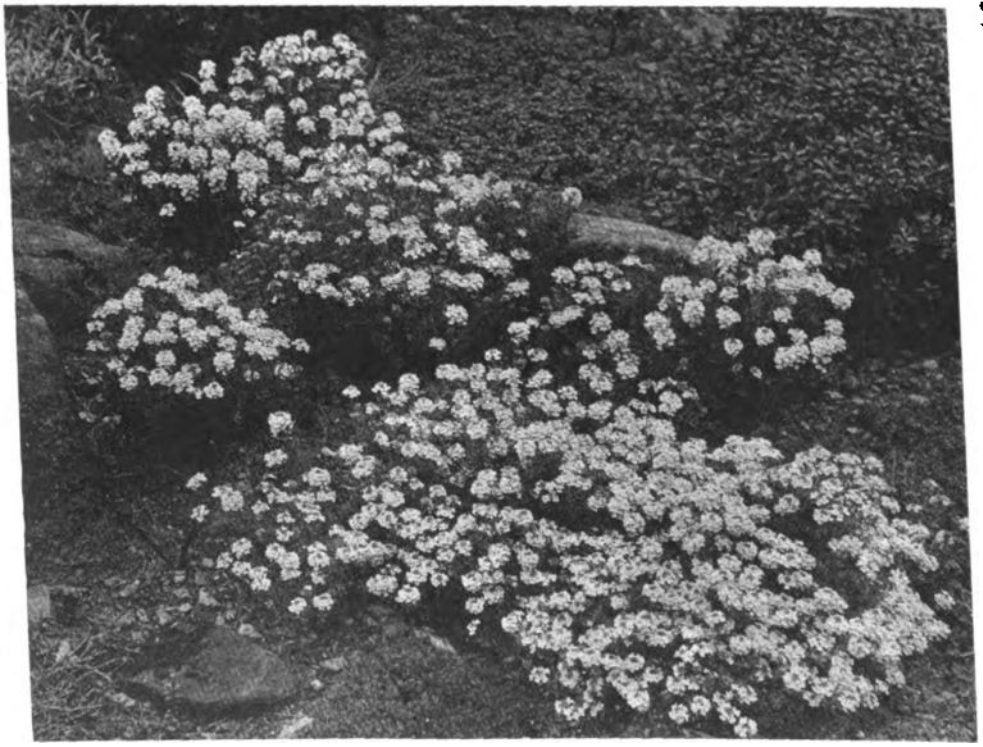
THE ÆTHIONEMAS.

A Desirable Plant for any Rock Garden.

AMONG plants suitable for rock and wall gardening the æthionemas hold a high and prominent position, largely on account of their long flowering period, which extends from May till July. They belong to the Natural Order Cruciferæ, and some half-dozen useful species and hybrids are in cultivation. One of the best is grandiflorum with elongated racemes of handsome deep pink flowers freely produced, and perhaps rather crowded. Nevertheless, it is a beautiful plant, and the ovate oblong glaucous leaves are an additional charm. A native of Mount Lebanon, the rosy lilac Æ. cordifolium hails from Asia Minor and flowers in early summer. This species also has glaucous leaves. If afforded a somewhat dry, stony position, it is a true perennial; but if grown in rich soil and on flat ground it often dies out. An ally of the last-named plant is Æ. pulchellum, and it closely resembles that species. It has rosy purple flowers, and is rather prostrate in habit. It is a plant that ought to be in every rock garden.



ÆTHIONEMA WARLEY HYBRID, AN ADMIRABLE PLANT FOR THE ROCK GARDEN.

Two others call for special notice, *viz.*, Æ. Warley Hybrid and Æ. Warley Rose. Both are exquisite and desirable subjects, and the illustration depicts part of a fine clump of Æ. Warley Hybrid. It forms compact little bushes covered with rose-coloured flowers in May and June, and it is readily increased by cuttings during the summer months after the flowering period. An ideal companion to Warley Hybrid is Warley Rose. In the rock garden it grows freely and is compact in habit. The brilliant rose flowers are freely produced, and the late Mr. E. C. Buxton of Bettws-y-Coed considered it one of the best of all alpines. Certainly it is a decided acquisition, and it is suprising that the name does not appear more frequently in catalogues of hardy plants.

To grow the æthionemas successfully they must have ample drainage, otherwise the roots decay, the leaves fall, and the plants become unhealthy—a sure sign that the position is too damp. In most [illegible]s an ideal spot can generally be fou[illegible]nshine is essential, and when possible a sloping piece of ground or near some rock should be chosen. Here the necessary warmth and drainage will be found. The soil ought to be on the light side, and if the medium is at all heavy it can be improved by adding old mortar rubble, sand, and limestone chips. Light and rather poor soil is best for all the æthionemas. Not only will they succeed in dry warm positions on the rock garden, or sunny moraine, but also in walls. It is well known that it is advisable to insert the plants as the wall is being built, but even so it is always necessary to add others later on, and with the plants under notice they must be transferred to the chinks and joints between the stones when quite small. Another method which often proves successful is by sowing seeds.

The species can be raised from seeds sown in the spring, but those of hybrid origin and special varieties are increased by cuttings. These will readily form roots in a cold frame or hand light if inserted in sandy soil during the summer months. Here they should remain for the winter, to be transferred to their permanent stations in the spring.—T. W. B.

THE USES OF BALSAM.

A Good Bedding Plant.

ALTHOUGH balsams have always been widely grown by that section of the gardening fraternity classed as professional, they have never become really popular and are comparatively unknown among amateurs. Those who have to keep up a supply of blossom in a cool greenhouse know their value as pot plants; in the open they do exceedingly well in sunny borders when planted out fairly late in the season and well hardened off. The waxy flowers, the fleshy succulent nature of the foliage, give the plants a tropical appearance, while the colours, mostly shades of red, are of a charming brightness.

Balsams come on very quickly in the initial stages so that early sowing is not advisable as a rule. A sandy leaf-soil compost serves for the seed-pan; a genial temperature ensures speedy germination and a warm, humid atmosphere causes fast development. After that they need the usual run of treatment given to greenhouse subjects, but the compost should be a rich one containing a fair admixture of manure, hop manure or spent manure from a mushroom-bed. Six-inch or eight-inch pots are used for finishing them off. Never pot too firmly, and give the plants plenty of moisture. Feed plants coming into flower, for they respond more than many others. Though we have never grown them in composts enriched by the addition of artificials alone, we have seen first-class results in such a case, a point which may reassure amateurs who find manure difficult to obtain.

For planting out, the balsams must not be forced. Sturdy, short specimens grown in a cooler atmosphere than the pot plants are invariably best and, as balsams are tender subjects, the hardening process should be thorough. It is too dangerous to plant out before June. We in the north plant out during the second week of that month. Water may be required in the open, also and in dry, hot weather a good sprinkling overhead every evening is of the highest value.

Although the Holstii sorts are perennial, most growers raise new stock annually. The hybrids offer a very wide range of colouring. Sultani varieties are also very fine and prove to be both profuse in flowering and almost continuous. Of the true annuals, the camellia-flowered kinds are probably the finest, while the double rose-flowered sorts are sure to prove favourites. Our best bedders are the miniatures, which, though small, bear very large flowers in mixed colours.—CLYDESDALE.

ACTÆA RUBRA AND A. ALBA.

Two Attractive Baneberries.

TO those who are seeking an attractive addition to the herbaceous border, these two baneberries will prove most useful. They are pleasing in every stage of their growth. Coming through the soil in early spring, they remind one of some strong-growing fern, with a soft red tint. The foliage is light and graceful and both species have white flowers, which open in April and early May; these are in clusters at the ends of the stems. Their greatest charm lies in the berries; these are large and vivid red in A. rubra, but with A. alba they are a shiny white, each berry marked with a black spot, this striking contrast gives this plant the pet name of "Doll's Eyes" in Canada.

Visitors to these gardens never pass these interesting plants without comment. As far as my knowledge goes, they seem of easy culture providing the site is fairly moist and in half shade. The baneberries belong to the crowfoot family and reach 3ft. to 4ft. in height, being easily propagated by root division and seed. We have been most successful with the latter. When planted together these plants give a most pleasant combination.—R. MOORE.

SAXIFRAGA PELTATA.

IT is not every garden in which there is a suitable place for the great Saxifraga peltata; but where there is, it is a plant which ought not to be forgotten. In spring it sends up on long 2ft. or 3ft. stems, clad with bristly red, broad heads of big pink stars. These are followed by great notched shield-like leaves, which are about a foot across and rough surfaced, on 3ft. high stems. But to grow it to its full dimensions it must have plenty of moisture, and it is happiest and finest by the waterside, where it can send out its long, thong-like rhizomes to reach the water. Although a Californian plant, it is quite hardy and perennial, and is an excellent subject where bold effect by the water is desired.—S. ARNOTT.

MORE ABOUT THE CHELSEA SHOW

This is the second and final portion of our report on the exhibits staged at Chelsea Show, the first part of which appeared in our special number last week.

HARDY FLOWERS

(*Continued from page* 304.)

Messrs. Baker's were represented by a stately group, the bold spikes of delphiniums in leading sorts being very effective. Lupin Pink Pearl, the bronze Verbascum Cotswold Queen, the red Lilium Sappho, and Geum Orangeman were all worthy of special mention in a collection that contained many noteworthy plants for the herbaceous border.

Messrs. Bees of Liverpool had a gracefully set-up group, the centre comprised of Eremurus Elwesianus. Lilium umbellatum was good, as were also Campanula Telham Beauty, Thalictrum dipterocarpum, the bright pink Astilbe Rubin, and various irises and lilies.

The exhibit of Messrs. R. H. Bath of Wisbech contained a group of the pink Pyrethrum E. M. Robinson, a few showy gladioli, peonies and cannas. Other good pyrethrums were the bright red Comet and Mrs. B. Brown. Bowls of Scilla campanulatum in the front of the group, together with anemones, bright yellow trolliuses and irises, completed a seasonable display.

Messrs. Godfrey and Son, Exmouth, staged a group of their Campanula persicifolia Pride of Exmouth, a semi-double light blue variety that should find a place in every garden.

Especially attractive were Messrs. Downer's lupins. They are superb, the wonderful pink shades being nothing short of remarkable. A few of the best would include Goodwood, Marion Cran, Gladsome, Wanderer, Delight and Glamour, all of the pink persuasion.

Mr. J. C. Allgrove, Langley, Slough, had eremuri and peonies, with a number of shrubs. The eremurus was E. robustus magnificus, the tall stout spikes lightly arranged with bamboo foliage. A few lupins, Campanula Telham Beauty, and gerberas all helped to make a unique and delightful effect.

Messrs. Rich and Co., Bath, contributed a display in which Geum Princess Juliana, an orange variety, was noteworthy. Pyrethrums and lupins, such as the yellow P. Sunshine, were also on view.

A good selection of violas was staged by Mr. William Yandell, Maidenhead, but the cold wet season prevented the blooms being shown in tip-top condition. In spite of this, however, some fine blooms were to be seen in this exhibit, where upwards of forty varieties were staged. Moseley Perfection is a general favourite, and the showy yellow variety John Adamson is sure to become popular. Kathleen, shading to a plum colour with a creamy centre, is new; also Dunbryan, a deep mauve edge with lighter centre. The forms of V. gracilis were pleasant; also the dark V. Grundel. Good useful garden varieties are M. Mott, Royal Scot and W. H. Woodgate; these are suitable for bedding purposes also.

Mr. Clarke, Taunton, staged both bedding and exhibition violas in good condition. The blooms were clean fresh and tastefully set up. A few of the show varieties were John Adamson, Alex. Ramsay, a large dark striped viola which is new; also another fairly new one is Colin Storey, a beautiful deep rose. Kathleen, cream edged band of purple, is a favourite; also Donald McDonald, a cream with a broad band of azure blue. Useful bedding varieties embrace Bridal Morn, blue; Primrose Dame; Redbraes Yellow; and James Pilling, a blue edged white. A few pansies were shown, an apricot variety being worthy of a distinctive name.

Mr. John Forbes of Hawick had vases of violas in his collection, and the small alpine varieties, such as forms of gracilis and the pretty little Bluestone, were to be found in many exhibits of alpine and rock garden plants.

Mr. Herbert E. Longford, Abingdon, had seven circular beds of pansies, which showed a wonderful variety, both in colour and size of the blooms.

ALPINE PLANTS

The alpine plants at Chelsea were well up to the usual standard, and in spite of the difficulty caused by the postponement of the Show there was even less tendency than last year to supplement the legitimate rock garden plants by half-hardy species.

There were no very striking novelties, but there was a very pleasant appearance in force of one or two old but hitherto very rare plants, such as Viola pedata, Phyteuma comosum and Campanula Allionii. Viola pedata is distinct from the rest of the family in the carriage of its upper petals, which are laid back like the ears of a Belgian hare, giving the flower a sulky expression very different from the cheerful pertness of most pansies. It comes from damp sandy places in North America and is usually considered very difficult to grow: but a great many sturdy plants were shown by Messrs. Bowell and Skarratt, both of the lavender-coloured type and the fine variety bicolor, in which the upper petals are deep velvet purple.

Phyteuma comosum is rare in nature and very difficult to collect from the narrow rock crevices to which it is confined, but it is unexpectedly well behaved in cultivation, and deserves every encouragement for its strange beauty, which is quite unlike anything else in the rock garden. Farrer compared the flowers to a cluster of purple glass phials with the necks drawn out into slender horns. Strong clumps in full flower were shown by Messrs. Tucker of Oxford and Messrs. Prichard.

Campanula Allionii with stainless Canterbury bells seems to be coming into its own as a moraine plant; it was shown by Messrs Clarence Elliott and in the outside rock garden of Captain Symonds Jeune.

A plant that made its first appearance last year from Spain, Linaria supina nevadensis (or possibly L. melanantha) was shown by Messrs. Gavin Jones and Messrs. Bowell and Skarratt. It has the habit and about the same length of life and requirements as Linaria alpina, but the flowers vary from velvety black through chocolate to reddish brown in the seedlings which it produces very freely.

The indoor rock gardens were not quite so elaborately designed as usual; but Messrs. Wood of Ashtead made a long, showy bank, broken in the middle by a jutting piece of rock, covered with a large plant of Azalea balsaminiflora (roseiflora), almost prostrate

MR. F. WOOD'S INDOOR ALPINE GARDEN.

THE EXHIBIT OF ALPINES STAGED BY MESSRS. MAXWELL AND BEALE.

Digitized by Google

in habit and smothered with apricot pink camellia flowers. The collection included Primula secundiflora, the rare Saxifraga mutata with starry flowers of brownish yellow, Fuchsia procumbens, whose odd flowers look like extinguished fusees but are followed by more decorative berries, and Iris gracilipes.

Messrs. Gavin Jones had an interesting flat-topped mountain crowned by an old specimen of Picea obtusa nana showing up the clear pink of Saponaria ocymoides. The mountain slope was discreetly planted with Potentilla opaca, Vaccinium myrtifolium, the true Saxifraga valdensis and other rarities.

Messrs. Oliver and Hunter showed among their rare primulas a very fine albino of Campanula rhomboidalis, with frosty white bells; Viola septentrionalis; and the true Polemonium pumilum.

Against a dark background of old and twisted conifers Mr. W. E. Th. Ingwersen of Sharpthorne, Sussex, showed a collection of excellent forms of Ramond a pyrenaica, a large soft pink and a small elegant albino, both of which stand out in clear-cut delicacy of design against dark rough leaves, and a very large deeply coloured variety. Dotted about on a mossy slope were the true Saxifraga Mme. Nabiana, which is the most richly coloured of its group; a very interesting hybrid between Mme. Nabiana and S. Aizoon lutea, with cream-coloured flowers neatly spotted with crimson; the rare Aquilegia Reuteri, a dwarf and sturdy form of A. alpina; and Androsace geranifolia, with graceful heads of pink flowers whose stem turns into a creeping stolon when they fall.

Messrs. Bowell and Skarratt showed a particularly interesting collection of varieties; several of the terrestrial orchids in which the firm specialises, including the writhing green lizards of Himantoglossum hircinum; the very dwarf Dodecatheon integrifolia; Tulipa Sprengeri, in scarlet and gold; the carmine pink garlic Allium Ostrowskianum; Codonopsis ovata, whose greyish blue bells are strangely marked inside with orange and black and purple; the pearl pink Lewisa oppositifolia; and the two forms of Viola pedata.

Messrs. Tucker of Oxford showed the curious Sedum sempervivum, which looks like a pyramid of brownish red tiles carrying a spike of pink flowers; several very healthy plants of Androsace pyrenaica; Allium pedemontanum, one of the best of the garlics; and Phyteuma comosum.

Messrs. Clarence Elliott made a very charming rock garden with a grey mountain awave with the plumes of Saxifraga caterhamensis and terraces planted with Oxalis enneaphylla rosea; Mertensia primuloides, with brilliant sapphire blue forget-me-nots; the queer spurless columbine, Aquilegia calcarata, in dusky purple; the violet blue Gentiana pyrenaica; and the large milk white flowers of Ranunculus parnassifolius.

Outside the tent the new form of rock gardening introduced by the firm attracted a great deal of attention, and two stone sinks containing a miniature pinetum carpeted with thyme, a pair of kaleidoscopic pig troughs planted with purple orchis, golden Potentilla ambigua, crimson daisies, alpine pansies and veronica, a miniature alpine garden and the reproduction of an alpine lawn, were appreciated for their beauty as well as their originality.

Messrs. Wells showed, among other good plants, the rare Cyclamen balearicum, with prick-eared white flowers and the most handsomely marbled leaves of the genus.

Messrs. Scaplehorn showed Silene Hookeri which carries relatively enormous flesh pink flowers with deeply cut petals on a small neat rosette; and Tritonia aurantiaca, a remarkable South African bulb with orange trumpets which have a transparent window at the base of each petal.

Messrs. Maxwell and Beale made a little rock pool overhung by Cotoneaster thymifolia and backed with primulas in a garden containing Rosa alpina; an interesting new silver saxifrage "Esther," with flowers of old ivory; and the cherry red potentilla "Miss Willmott.

Messrs. Prichard showed Saponaria Weidmannianum, with clear pink flowers on turfy hummocks; Wahlenbergia serpyllifolia alba violacea, which, in its best form, is neatly striped with violet on palest lavender; Phyteuma comosum; Smilacina bifolia, with deep green leaves and fluffy spikes of creamy flowers—a minute and very charming woodlander.

Messrs. Reuthe included our rare native Orchis militarus; the very sombre slate blue Globularia stygia; Veronica filiformis, a delicate little bush with needly leaves and blue bird's-eye flowers; and the rare Japanese alpine Conandron ramondioides, with fleshy crinkled leaves and lavender potato flowers.

Messrs. Jeans and Trowbridge showed a very attractive form of the native Silene maritima, with flowers faintly flushed with pink; and the not very hardy Agathæa cœlestis, crowded with lavender blue cineraria flowers.

The Colesborne Gardens showed several rare and very desirable plants; a fine single white form of Pæonia arietina; Corydalis Wilsonæ, with chrome yellow flowers and grey, bronze-shaded foliage; Anemone rupicola, with large solid white flowers; and the tall greyish violet Globularia tricosanthe.

A magnificent show of new primulas and meconopsis was staged by Lady Aberconway and the Hon. H. McLaren. These were mostly collected in Sikkim and Tibet by Capt. Kingdon Ward. Among the newer species, P. Pauliana, a yellow of the geranioides section, may become a good garden plant. As shown, the growth was according to the type smaller than it should be. Probably Capt. Kingdon Ward's greatest find is P. Florindæ, a giant sikkimensis with the typical citron yellow flowers. It is so large that it ably lives up to its name of the Cowslip Primula. Among the meconopsis the new M. Baileyi, a good blue faintly flushed with purple, and M. paniculata, a fine yellow, were the most striking.

Messrs. Storrie and Storrie had a fine exhibit of polyanthus and aquilegias a very fine combination, by the way. Their strain of polyanthus is so well known that it was pleasant to see that it was better than ever. The colours were clear and attractive, particularly in the paler shades.

Among other alpines, Messrs. Oliver and Hunter showed a fine collection of primulas. They also showed P. Florindæ in even better form than those in Lady Aberconway's exhibit. They also had a dwarfer sikkimensis, P. flexilipes, of a very pale yellow, and the popular giant form of P. Littoniana.

Mr. G. H. Dalrymple again staged his well known Bartley strain of P. pulverulenta. This has the advantage of coming true from seed, as well as being a very pleasant pale pink with a deep crimson eye.

THE SERRIED RANKS OF TULIPS ON THE STAND OF MESSRS. BARR.

TULIPS

The postponement of the Chelsea Show for a week no doubt made a decided difference to the exhibits of May-flowering tulips; but still there were one or two creditable displays, while a few exhibitors staged vases of useful flowers in their miscellaneous groups.

Messrs. Barr and Sons of Taplow and London were represented by an exhibit characterised by the fine bold flowers on stout tall stems. The arrangement was also good; it consisted of three prominent groups of tulips with the intervening spaces or bays filled with various irises, while in the front of the group were anemones, muscari and Schizostylis Mrs. Hegarty, a rose pink form of the Kaffir Lily. A few strong spikes of eremuri and gladioli were also staged. However, the tulips were the principal feature, and the following were especially noteworthy: The handsome and popular Darwin Tulip Farncombe Sanders was well shown, also Mme. Krelage, Bleu Aimable, mauve shaded purple; the striking Old Times, an improvement on Amber Crown; Boadicea, rosy red flushed amber; Goldfinder, a lovely tulip of perfect form, clear scarlet with pure yellow centre; the distinct and dark Mrs. Potter Palmer; and Andromaque, a large and beautiful flower, brilliant garnet red in colour. Other varieties were on view, and collectively the display was bright and very effective, the colours being well arranged.

Messrs. Bath, Limited, Wisbech, had a few vases of tulips with their herbaceous

Digitized by Google

plants, and they included the striped and quaint Goldmine, F. Sanders, and the beautiful Parisian Yellow.

Another glorious group came from Messrs. Dobbie, Limited, Edinburgh, arranged in vases so that each variety was an exhibit in itself, and every flower could be seen to advantage. Asparagus Sprengeri was used to cover the vases, etc., and this added much to the general beauty of the display. As a whole the flowers were good, the stems strong and the foliage healthy. A few outstanding vases were Inglescombe Yellow; Pride of Haarlem, a grand variety with brilliant cochineal-carmine large flowers of exceptionally fine form; Mrs. Moon, a large canary yellow variety; Marksman, a brilliant orange scarlet slightly shaded buff, with a strong constitution; Orange King; and Gorgeous (syn. Lucifer), a handsome tulip with dark cherry scarlet flowers flushed with deep orange on the inner sides. At the end of the tulip stand was staged a batch of well grown calceolarias, with fine pouches and showing great variation in colour. The whole proved attractive to numerous visitors.

Messrs. E. Paul and Co., Cheshunt, put up several vases of bright tulips in their general group—Scarlet Perfection; Marksman; the handsome old Dutch tulip Dom Pedro; and two others in the same category, viz., Panorama, dull madder red with rosy glow; and the large Turenne, a stately flower which is purple margined with amber.

Messrs. H. G. Longford, Abingdon, Berks, skilfully arranged a circular bed on the floor, which contained a few tulips in addition to pansies, iris, spiræas and other subjects. The principal vases contained flowers of T. Ellen Willmott, Walter T. Ware, Juliet, and the yellow Alaska.

LILIES

Once more Messrs. Wallace had matters more or less their own way in the field of lilies and they spared no pains in staging one of the finest exhibits of this fine garden flower that has been seen at Chelsea in recent years. The lily garden was tastefully set out in beds, each containing something fine in the species and varieties. In the beds the chaste beauty of the lily was well seen through the informal grouping. One commenced with a bold coloured colony of Lilium umbellatum Diadem, and the graceful L. elegans alutaceum, stretching through the more handsome splendour of L. umbellatum spendidum to the tall and elegant L. croceum, with its orange blossoms spotted with brown. Beautiful as these species are, however, they must bow to the glorious LL. Brownii, regale and ongiflorum giganteum. One of the latest Japanese lilies to be introduced into this country was also to be seen. This is the dainty alpine species, L. rubellum, so characteristic with its few broadly stalked leaves and its pure rose pink fragrant flowers. The elegant Martagon section was well represented in bold groups of the dark toned dalmaticum, the lighter coloured Mrs. R. O. Backhouse and the glorious pure white album.

DAHLIAS

It is as yet early in the season for dahlias and the exhibits of this flower were few in number. The two largest stands were put up by Messrs. Carter Page and Co. and Messrs. J. Cheal and Sons. Dahlias of every type and in many colours were arranged side by side. Messrs. Carter Page's exhibit was exceedingly good when one considers that we are only now into beginning of June. The pompon and decorative varieties were in good form. Johan Mensing, a decorative dahlia of deep scarlet crimson; Pride of Berlin, a pretty pink star dahlia; Feodora, a miniature decorative; Murillo, a rosy pink decorative with a silver sheen; and Canary, a large sulphur yellow cactus-flowered variety, were a few noteworthy dahlias on this stand. Messrs. J. Cheal showed several of the popular Mignon varieties and many of their well known star dahlias. Among these were Crawley Star, Gatton Star and White Star. Arthur Hutton is a good terra-cotta decorative dahlia of large size, and Tipsy, a camellia dahlia of brilliant scarlet. Such varieties as Mrs. Bigg, Alma and Dulcie were also noted.

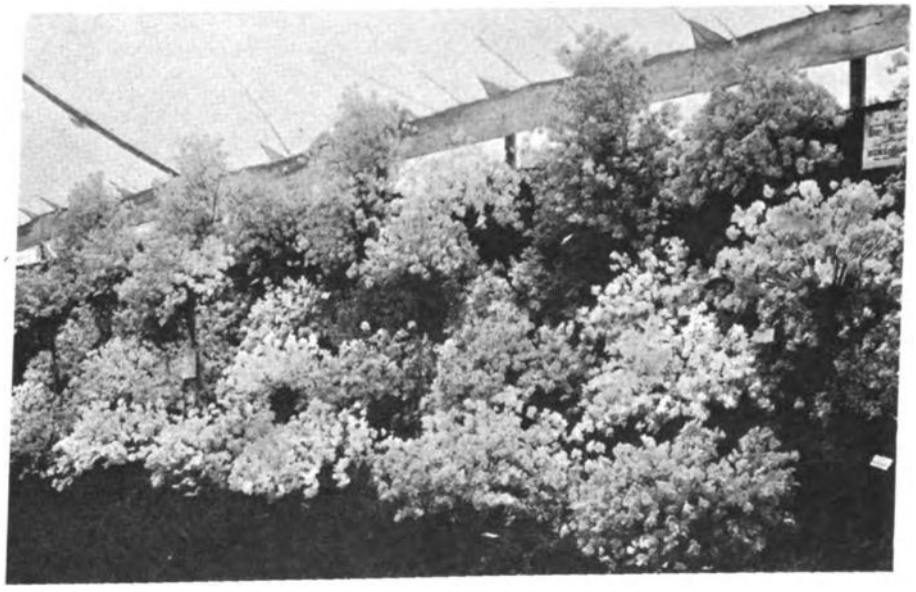
SWEET PEAS

The general high standard of the Show was fully maintained by the exhibitors of sweet peas at Chelsea last week, when these delightful, fragrant flowers were displayed in great beauty. Mr. Robert Bolton is a past master in the art of setting up graceful exhibits of sweet peas, and on the present occasion the critical visitors were of the opinion that he excelled himself. Floral decorators and public speakers have, at least, this much in common: the most successful is he who knows when to stop. This, Mr. Bolton has long since learnt, or, more probably, inasmuch as artists are born and not made, knows instinctively when the maximum effect has been obtained, and so gives delightful displays of his sweet peas.

Not only was it an artistic group, but the flowers were of supreme quality, such as one would expect at the Summer Show of the National Sweet Pea Society when the season is at its height, rather than in the spring. Magnet, as shown by Messrs. Robert Bolton and Son, was decidedly the novelty sweet pea of the Show. Structurally it has all the qualities of the highest class flower, and its glowing pink shades of colour are most charming. The large quantities that Messrs. Bolton set up show that it is a free-flowering variety, for it is an axiom in the sweet pea world that any variety which will flower freely under glass is certain to be more floriferous out of doors. "What Joy," if Mr. Bolton will forgive us, is not a pretty name and is unworthy of the excellent creamy yellow novelty which he showed so well. Picture, which was shown in several baskets, is one of the finest sweet peas extant and is of fascinating rose-flushed, flesh pink colouring. Other desirable varieties in the Bolton collection were Gold Crest, of rich orange colouring lightly tinted with salmon; Mammoth, a fiery orange scarlet flower, with rather more scarlet than orange, and of immense size; Grenadier has nearly the true scarlet of the Guardsman's tunic, and it keeps its colour well out of doors; Royal Mauve is of lovely shading; R. F. Felton, though fifteen years old, is still one of the very best lavender-coloured sweet peas.

A regal collection of sweet peas was arranged by Messrs. Dobbie and Co. next to their glowing tulips. Their sweet peas were imposing in their great quantity, as well as in the quality of the flowers and their wonderful colour value. The orange and orange scarlet varieties were especially brilliant and of these the outstanding were Wizard, Royal Sovereign and Tangerine Improved. Various shades of pink were also admirable. There were, to select from, Mary Pickford, Hebe, Miss California, Dignity, Renown and Patience, all of pink shades of colour, but all distinct and equally desirable. Jean Ireland, raised at their Marks Tey grounds some years ago, is still one of the very best picotee-edged varieties, and Constance Hinton occupies a similar position among the white sweet peas. Royal Purple, with Mrs. Tom Jones and Gleneagles of blue colouring were delightful, while their novelty Marchesa, of creamy yellow shading, and Mermaid of mauve tone, have great decorative value.

As corner pillars to their most charmingly arranged garden in the tent Messrs. Carter and Co. had many beautiful sweet peas. Mrs. A. Searles, one of the novelties, is of bright coral colour shaded with salmon.



MESSRS. BOLTON'S MAGNIFICENT DISPLAY OF SWEET PEAS, PROBABLY THE FINEST WHICH HAS EVER BEEN SEEN AT CHELSEA.

STOVE AND GREENHOUSE PLANTS

As a whole, these constituted a glorious sight, and, although the former were but sparsely represented, the latter were well shown and in great variety. It proved what a wealth of material there is to choose from for the cool greenhouse, and how a wonderful display can be secured without much fire heat, and, moreover, little difficulty will be experienced in growing them to perfection.

Digitized by Google

Few ferns were on view, but the group of stove and greenhouse varieties set up by Messrs. Ellison, West Bromwich, were well grown, clean, and exceptionally fresh in appearance. Upwards of seventy varieties, including all the popular forms, could be seen—selaginellas in various species and varieties, while here and there were fine examples of Saxifraga sarmentosa tricolor.

Messrs. Webb and Son, Stourbridge, occupied a corner space, and here they used everything to the best advantage. There were grouplets of blue and gold salpiglossis—and here we might say what an excellent pot plant this beautiful annual makes: every owner of a cool greenhouse should give it a trial; also Linaria hybrida and double scarlet clarkia. Large drifts of cineraria, which embraced the florists' varieties stellata and cactus, all of which displayed a wide range of colour. Here and there were slight depressions in the arrangement, and these were filled with calceolarias, well grown and choice strains of schizanthus, superb gloxinias, Primula obconica and Rhodanthe maculata. Other fine things were included, and the exhibit did this well known firm great credit.

Messrs. Toogoods, Southampton, were represented by a pretty group, the centre of which was occupied with a bold group of Cineraria stellata of more than average merit. Each end was filled with schizanthus, beautiful stocks, Nemesia Blue Gem and N. strumosa. Banks of blue, white and yellow iris were effective, also Calendula officinalis King Edward VII, a great improvement on the type. The orange giant mignonette deserves more than the ordinary meed of praise; it is an excellent kind, well grown, the large spikes of bloom being the envy of many who have repeatedly failed to grow this annual in pots successfully.

Among greenhouse flowers the homely geranium or pelargonium occupies a high position, and these general favourites were well shown by one or two firms. Messrs. Jarman and Co., Chard, staged exquisite blooms in their usual effective way, and among the single varieties we noted General Wolseley, clear rosy red; Bombay, somewhat similar, with a pure white eye; Edward Hockey, salmon; Sir E. Cassel, brilliant scarlet. The doubles were represented by Paul Rubens, dark red; Lave, orange scarlet; and August Rickards, bright scarlet. Several sweet-scented and oak-leaved varieties were there, with small flowers, also a pretty display of alpine violas of the gracilis type.

Messrs. R. J. Case, Taunton, in addition to large pans of the scarlet Salvia splendens Harbinger, put up vases of zonal pelargoniums, such as the bright Drummer Boy, a warm salmon red single; The Speaker, a fiery salmon semi-double; and President Baillet, a semi-double soft red. An edging of variegated nepeta contrasted with the pelargoniums, which were tastefully arranged.

Mr. F. A. Denny (gardener Mr. Thrower), Horwood House, Bucks, set up a group which contained well grown examples of Calceolaria Clibrani and Statice profusa hybrida. All were flowering profusely.

The hydrangeas have made remarkable progress during the last few years, and a few firms appear to make a speciality of these plants, especially H. J. Jones, Rycroft Nurseries, Lewisham. He staged two wonderful groups, the fine heads of blooms, in various shades of pink and blue, were the admiration of many; while the white varieties were very chaste. The arrangement was perfect. Grevillea robusta broke up the flatness of the floor group; but the huge bank at the side of the tent presented a pleasant and wonderful sight, the shades of colour being so arranged to produce a harmony agreeable to the eye.

From Studley College came a group of hydrangeas, chiefly of the white and blue persuasion. It needed a few pink varieties to liven up the general display, otherwise the plants were well grown.

An unusual and interesting group was staged by Messrs. Low of Enfield, inasmuch that it contained a large number of Australian and New Zealand hard-wooded plants. Acacias were well represented, also the bottle-brush tree, Metrosideros floribunda, the reddish brush-like inflorescence being most showy; Boronia heterophylla, well berried; pink hydrangeas, the scarlet Clerodendron fallax, a good selection of hippeastrums, some of the flowers being round and beautiful in outline; the golden Calla Elliottiana; bold scarlet antirrhinums; and other similar subjects, all welded together into one harmonious group.

Messrs. Godfrey and Son, Exmouth, Devon, had a table of dwarf schizanthus from which all the pale and worthless forms had been eliminated. The strain is characterised by the compact habit, variety and richness of colour, and the free-flowering qualities of the plants.

A decided departure from the usual run of exhibits was that staged by Messrs. L. R. Russell of Richmond. Reminiscent of bygone days, it is nevertheless pleasant to see that there is still a demand, if slight, for this type of plant, *viz.*, the occupants of the greenhouse known as the stove. Here we saw in the finest conditions such subjects as caladiums, anthuriums, richly coloured crotons, the nepenthes with their quaint pitchers, dracænas and other beautiful foliage plants. The flowering examples included Clerodendron Balfouri, large specimens of Medinella magnifica, and the showy Francisca calycina major. The usual array of palms, ferns, etc., contributed towards making this group a feature of the Show. Near-by some beautiful tree ferns were on view, all from Mr. Russell.

The collection of caladiums from Mr. H. B. Brandt (gardener, Mr. H. Cook), Nutfield, Surrey, was remarkable for the variety, colour and healthy appearance of the plants.

The Cheadle Royal Mental Hospital, Cheshire, was responsible for a group of Senecio glastinifolius, a beautiful pink cineraria-like flower, rather larger than the stellata type, while the plants shown were 2ft. to 3ft. high in 5in. and 6in. pots. It appears to be the same as Senecio multibracteatus, and ought to prove one of the most popular of greenhouse plants, while for the hybridist it may prove a useful parent.

Messrs. Blackmore and Langdon's begonias were among the finest exhibits in the Show. The plants were pictures of health, and the massive flowers perfect. Although they were large, they lost none of their beauty on that account, and it is the best lot of begonias we have seen for a long period. The Bath firm has specialised of late years in varieties suitable for baskets, and here several forms were on view. Among the large-flowered section we noted James Braid, Sir H. Willcox and Calthorp, all reds; Queen of the Belgians, Mrs. D. B. Crane and Hilda Langdon, pinks; while Albatross is a superb white.

Messrs. Watkins and Simpson, London, put up a useful lot of Schizanthus wisetonensis Excelsior strain, and the new bedding Calceolaria Albert Knight, which has yellow and bronze pouches rather larger than the usual bedding varieties.

Messrs. Sutton and Sons, Reading, on the present occasion appear to have excelled all their previous efforts, for they put up a most meritorious lot of plants. The original plot, probably square, had been converted into a veritable fairyland, with banks and bays of flowers cunningly arranged with paths intervening, so that there were surprises for the visitor at almost every angle. A few palms had been judiciously placed, and the tent poles draped and clothed with trailing begonias; while the pink Senecio multibracteatus graced a pole at one corner. The chief plants in this noteworthy and excellently arranged display were cinerarias in almost endless variety, both in colour and general habit; Calceolaria Clibrani, together with the large-flowered hybrids; exquisite streptocarpus; wonderful gloxinias characterised by their massive foliage and flowers; begonias in variety; schizanthus in all shades and habit—and we would particularly call attention to S. retusa, a pretty shade of rose, and the retusa hybrids; salpiglossis was well shown, also the John Innes strain of calceolarias. A touch of brilliance was furnished by Clerodendron fallax, which constituted a prominent group near one corner. All the above were present in large masses, and were so arranged that the whole presented an exquisite and beautiful group. Near by, the same firm had a large circular bed filled with Primula obconica, each distinct shade being given a block to itself. This group was awarded the Sherwood Cup.

Messrs. Peed, West Norwood, arranged a group having large palms at the back, the front portion being filled with bold blocks of blue hydrangeas, streptocarpus, gloxinias,

A SECTION OF MESSRS. SUTTON'S EXHIBIT OF GREENHOUSE FLOWERING PLANTS WHICH WAS AWARDED THE SHERWOOD CUP.

Digitized by Google

caladiums (for which this firm is famous), liliums, and a small patch of the pinkish Kalanchoe flammea.

Messrs. Carter of High Holborn and Raynes Park produced quite one of the leading exhibits at Chelsea, but it would probably have been improved by a path or two, so that visitors would have had an opportunity of seeing the flowers to better advantage. However, it was tastefully arranged, and the sweet peas were much admired. This exhibit was divided up into squares, bays, beds, mounds, etc., and each area was devoted to some particular plant. Thus, there were large spaces filled with cinerarias, gloxinias, begonias, statice, salpiglossis, antirrhinums and similar subjects. Altogether, it was a fine exhibit, carefully planned and arranged, and all the various strains of plants shown bore signs of careful selection and cultivation.

FRUIT & VEGETABLES

One of the most tempting displays in the Show was the magnificent collection of strawberries staged by Messrs. Laxton Brothers. All the varieties exhibited showed fruits of good size and colour and all were in the best of condition. Their variety The Duke, one of the best early strawberries yet raised, was well shown, and supported by others such as Majestic, a good cropper with fruits of fine flavour; Laxton's Prolific, another heavy cropper; and King George, which even surpasses Royal Sovereign in cropping and size of fruits.

A large and varied collection of fruit trees in pots was staged by Messrs. T. Rivers and Son. Here were to be seen peaches nectarines, plums and cherries. The most notable sorts shown in peaches were the Duchess of Cornwall and Peregrine; while John Rivers and Early Rivers were two good early nectarines. A fine plant of Cherry Guigne Annonay was also shown.

The magnificent exhibit of apples by Messrs. Bunyard attracted a great deal of attention, and not a few were greatly surprised to see the fruits in such perfect condition after almost nine months' storage. It stands as a lesson in the keeping capacity of several varieties of apples, notably Cox's Orange Pippin, Allen's Everlasting, Sir John Thorneycroft, Lane's Prince Albert, Chaplin's Pippin, Sturmer Pippin and Wagener, all of which were displayed among the seventy to eighty varieties shown in perfect colour and form.

There were several fine displays of vegetables, of which once more that of Mr. Vicary Gibbs (gardener, Mr. E. Beckett) led the field. The stand included excellent dishes of almost every vegetable it is possible to have on our table during the summer months. The variety shown and the perfect condition of each, together with the praiseworthy method of staging so characteristic of Mr. Beckett, reflected the greatest credit on the whole staff of Aldenham House gardens.

Baron Bruno Schröder also staged a meritorious group, including radishes, celery, cucumber, broccoli, tomatoes, etc., all of really high-class merit. The exhibit of Messrs. Sutton's also showed that our large seedsmen consider the vegetable side to be as important, if not more so than the floral side of their business. There were many choice kinds on view, and all showed the results of careful handling and attention.

CACTI

Several exhibits of cacti were staged, and many visitors paused to examine the quaint and varied forms of these succulents. Miss Worth of Holebeach had a most interesting collection, including a number of rare specimens, some from Mexico and others from East Africa. A few of them were in flower, and all were in excellent health. Mamillarias, such as M. chionocephala, M. molle and M. plumosa, were among the group. Echinocacti of all kinds, a few haworthias and numerous other cacti were also to be seen.

Mr. Sydney Smith of Enfield had a large number of cacti on show, the majority of which were growing in pots. A few of the smallest were cleverly arranged as cacti gardens growing in bowls. Mamillaria Schmidtii, M. rhoptha, the snake-like growths of Cereus flagelliformis, and C. serpentinus, Echeveria Desmetiana, E. farinosa and Euphorbia Caput-Commelini all added interest and variety to the group. Messrs. H. Hemsley showed a number of vigorous cacti among their group of hardy plants.

MESSRS. LAXTON'S TEMPTING DISPLAY OF STRAWBERRIES.

ORCHIDS

The Orchid Tent was so arranged that exhibits were only placed round the sides, the central part being entirely free and thus much more space for visitors was allowed than in former years. This new method met with general approval.

Messrs. Charlesworth and Co., Haywards Heath, had a remarkably fine group in which their premier strain of Odontoglossum crispum stood out prominently. A large number of odontiodas made a pleasing contrast with their many-flowered spikes of scarlet and red colours. Touches of bright yellow were seen in Odontoglossum Phillipsianum aureum and in O. Wilckeanum aureum, both home-raised hybrids. Lælio-Cattleya Fascinator rosea was the best of the section, while smaller plants of Sophronitis parentage were in the front. Several novelties were staged in odontonias, of varying rose and purple colour, which when fully grown will be very effective. The popular Oncidium papilio with its butterfly-like flowers poised on long stalks, was a continual source of attraction as also was the curious Bulbophyllum virescens, with an umbel of eight flowers.

Messrs. J. and A. McBean, Cooksbridge, had an extensive display, which, as usual, was most artistically arranged, every plant showing to advantage. The central part was composed of Cymbidium hybrids intermixed with odontiodas and light oncidiums. At various points were well flowered plants of Cattleya citrina, as well as of Lælio-Cattleya G. S. Ball, the numerous flowers of which made masses of bright orange yellow colour. Odontoglossum crispum has always been a speciality of the firm, and many beautiful varieties were again staged. Epidendrum vitellinum and Cypripedium Maudiæ came in for well deserved appreciation, as also did several distinct hybrids of Miltonia vexillaria.

Sir Jeremiah Colman, Bt., Gatton Park, Surrey, had a most interesting group of rare species and elegant hybrids. Of chief importance were the numerous varieties of Lycaste Skinneri, which were mostly staged in specimens bearing from five to seven flowers. Lycaste lanipes, with six cream-coloured flowers; and L. lucusta, of dark green colour, were also included. A beautiful rarity was seen in Vanda suavis alba, the flowers being only obscurely spotted with light yellow. An attractive plant was staged in Sarcopodium Lyonii, perhaps better known as Dendrobium acuminatum, with flowers of carmine rose. Along the front row were the pretty Vanda parviflora, Cypripedium niveum and several well flowered examples of Cypripedium Maudiæ.

Mr. H. T. Pitt, Stamford Hill, was awarded the challenge cup offered by members of the orchid trade, as well as a silver-gilt Flora medal. His group contained many interesting as well as rare species, and he also staged more cattleyas than other exhibitors. The scarce Bulbophyllum macrobulbon was well flowered, as also was Renanthera Imschootiana, with numerous flowers of red colour. In addition to Anguloa Clowesii, popularly known as the Cradle Orchid, there was a plant of the much rarer A. uniflora. The central part was made up of several plants of Microstylis Scottii, the quaint Nanodes Medusæ and the green-coloured Lycaste Locusta.

Messrs. Cowan and Co., Southgate, had many fine cypripediums in their group, mostly of the albino section, such as Maudiæ, Emerald, Curtisii Sanderæ and callosum Sanderæ. In the centre was a showy plant of Lælio-Cattleya Queen Mary, with five large flowers of mauve purple, and just at the back Selenipedium macrochilum, with its elongated petals. Odontoglossum Stanley Baldwin had six large flowers blotched with violet, and a novelty was staged in O. Southgatense (Gorizia × Georgius Rex). Among the many odontiodas mention may be made of Cordor, with a branched spike of reddish flowers, and of Jessica, with soft rose-coloured markings, also of Murillo magnifica, with a spike of twenty flowers of scarlet red.

Digitized by Google

Messrs. Sanders, St. Albans, had an extensive display in which were many plants of the charming Cattleya citrina, with pendulous flowers of citron yellow. An elegant, as well as rare, plant was staged in Ærides Houlletianum; while along the back row were well flowered examples of Thunia Brymeriana and numerous cymbidiums, mostly of the insigne section. In front were Bulbophyllum Lobbii, and its variety Colossus bearing larger flowers. Phalænopsis amabilis stood out prominently with its large white flowers of moth-like formation.

Messrs. Stuart Low and Co., Jarvis Brook, Sussex, put up a fine exhibit, comprising many cypripedium species and hybrids, and a number of odontoglossum hybrids, white and coloured forms being equally represented. Peristeria elata, commonly known as the Dove Orchid, came in for its due share of appreciation; while in other parts we noticed Cœlogyne pandurata, sometimes referred to as the Lizard Orchid, and Dendrobium atroviolaceum. This exhibit was specially good in the oncidium species, perhaps the best example was O. serratum; and there was also a many-flowered plant of the garden-raised hybrid known as O. McBeanianum (macranthum × superbiens). Cattleya Skinneri alba, with its white flowers, made a pleasant contrast to the purple-coloured ones Cattleya Tityus.

Messrs. Armstrong and Brown had an effective arrangement of cypripediums, including Gold Mohur, Lady Rowena and Curtisii, the latter bearing a dozen well developed flowers. A fine effect was produced by massing several plants of the blue-flowering Dendrobium Victoriæ Reginæ. Odontoglossum crispum xanthotes looked very pretty alongside of the heavily blotched Odontoglossum Victory; while just in front was a superb example of Cattleya Mossiæ var. Reineckiana with nine large flowers. Sarcopodium Lyonii was also well staged. Selenipedium caudatum, with its long-tailed flowers, and Cœlogyne pandurata, of greenish colour, attracted no small amount of attention.

Messrs. Black and Flory, Slough, staged numerous Miltonia hybrids of the vexillaria section; also a finely flowered example of Dendrobium Thwaitesiæ, with flowers of golden yellow. Cattleyas were the outstanding feature, and included some richly coloured varieties of C. Prince Shimadzu, as well as of a hybrid named C. Chelsea.

Messrs. Cypher and Sons, Cheltenham, had an extensive display of cypripediums, including such popular kinds as Chamberlainianum, Gowerianum and Lawrenceanum. At the back was a tall plant of the scarce Dendrobium Dalhousieanum luteum, and in front of it some well flowered examples of D. atroviolaceum. Selenipedium macrochilum came in for notice on account of its unusually long-tailed petals. Lælia purpurata, so popular in the old Temple Show days, was here in evidence, also the best of its hybrids in Lælio-Cattleya Aphrodite.

Messrs. Mansell and Hatcher, Rawdon, Yorks, had a pretty group of miltonias, including the one known as "J. Gurney Fowler," white with a dark blotch on the labellum. Cattleya Mossiæ was in fine form, and among the cypripediums were Gowerianum, Lawrenceanum and the ever popular Maudiæ.

Messrs. Sutton Brothers, Hassocks, Sussex, staged a pretty group containing the white-flowering Cattleya Dusseldorfei and Phalænopsis Rimestadiana. At one end was a large plant of Dendrobium thyrsiflorum, and at the other the pretty Epidendrum vitellinum.

Mr. Harry Dixon, Wandsworth Common, had an effective exhibit comprising many attractive odontoglossums and odontiodas. Cattleya Mossiæ and some of its hybrids made useful plants; while Fowler's variety of Cypriepdium Rossettii stood out prominently.

NEW & RARE PLANTS

FIRST-CLASS CERTIFICATE.

PRIMULA FLORINDÆ.—One of the most recent acquisitions to the genus primula. This species was collected by Captain F. Kingdon Ward in 1924 and the plants shown are the first to flower in this country. It can best be described as a giant sikkimensis of erect and columnar habit—its tall flowering stem bears a loose head of dangling citron yellow bells. The most striking feature of the plant, however, is its large foliage, entirely different from sikkimensis. The leaves vary from broadly ovate to cordate depending on how the plant has been grown, and are exceedingly handsome. It is a plant which seems to vary a great deal in response to growing conditions and may be seen entirely out of character with the type as found in Tibet. It should prove a popular garden plant when once it gets into more general cultivation. Shown by Messrs. Oliver and Hunter, Moniaive, Dumfriesshire.

CELMISIA HIERACIFOLIA.—A pleasant looking species of those large rather stolid looking daisies of New Zealand. The individual flowers are about 3ins. across and pure white with a yellow cushion centre. The ray florets are long and narrow and give, in the mass, a fine, feathery appearance, which is greatly enhanced by the handsome lanceolate, toothed foliage, with its pure white reverse. Shown by Lady Aberconway.

CARNATION HEBE.—The fine upstanding cushion blooms of a crushed strawberry colour attracted considerable attention. They were of medium size, but of perfect form and texture. The calyx was firm and held the petals well. The flowers are well carried on tall, graceful stems and the foliage was in perfect condition.

C. DORCAS.—A really first class variety whose perfectly formed blooms are of a rare shade of dark maroon, which changes with intensity and manner of lighting. The blooms are firm in texture and well set on elegant flexible stems. These two carnations were shown by Mr. C. Engelmann.

IRIS WATBRACT.—A dainty hybrid variety between I. Watsoni and I. bracteata, which has happily combined the characteristics of the two parents. The stem is only from 6ins. to 8ins. in height and bears single flowers. The colour of the flowers varies considerably, from a deep violet purple to the palest flesh colour. In the centre of the falls towards the base there is a lighter coloured patch with markings and dark veinings reminiscent of a viola. The standards are of a delicate transparent violet which shows the veining to advantage. Shown by Mr. Amos Perry.

AZALEA KNAPHILL WHITE.—The individual blossoms are borne in a loose formation so that each stands out on the plant like a glistening, transparent wide-open bell. The colour is pure snow white save for a feathery

AN ADMIRABLE ALPINE DAISY FROM NEW ZEALAND, CELMISIA HIERACIFOLIA.

AWARDS OF MERIT.

PRIMULA CAWDORIANA.—A dainty little species of the "soldanelloides" section with a tight head of a few flowers borne on long, columnar stems arising from a basal rosette of small, neatly stalked leaves. The length of the corolla tube, which is deeply cleft is one of the features of the flower as well as its colour, which is a delicate violet.

P. FLEXILIPES.—This is yet another elegant member of the valuable sikkimensis group. It is really a miniature replica of sikkimensis. The flowers dangle gracefully from their loose cluster, are sweetly scented and pale yellow in colour. The foliage is neat, but short.

CAMPANULA CRENULATA.—A splendid rock garden species of neat and graceful habit. A single deep blue open bell flower is carried at the end of each stem, which is some 6 ins. high. The foliage shows the characteristic campanula variation.

ROSCŒA CAUTLEOIDES VAR. BEESII.—There seems to be little difference between this

Digitized by Google

blotch of yellow in the rear petal. Shown by Mr. Hosea Waterer.

A. KNAPHILL PINK.—A very fine variety similar to the last in habit and floriferousness, but with blossoms of varying shades of pink, all with an orange yellow blotch. The foliage was fully out at the same time as the flowers and greatly added to the appearance of the plant. Shown by Mr. Hosea Waterer.

ROSE GOLDEN SALMON.—A very fine dwarf perpetual-flowering variety carrying deep salmon pink blossoms. The blossoms are carried loosely on the plant which appears floriferous. The foliage is good and of a pleasant shade of green. Shown by Messrs. Cutbush.

PELARGONIUM GODFREY'S MASTERPIECE.—The flowers of this variety attracted no little attention on account of their striking colour, made up of a ground of deep crushed raspberry pink overlaid with almost purple blotches on the rear petals, which provides a vivid contrast in the flower itself. The petals are waved and rather decorative. Shown by Messrs. Godfrey, Exmouth.

MELALEUCA LATERITIA.—This was one of the most striking plants of the Show. In appearance it is a shrub of the most graceful habit, with long slender, feathery branches, which bear the cylindrical spikes of rich scarlet flowers. It is not a glaring scarlet, but rather soft in tone. Shown by Rev. A. T. Boscawen.

CALLICOMA SERRATIFOLIA.—This shrub grows out of doors in Tresco Abbey Gardens, but is really an evergreen greenhouse shrub. It is most ornamental, with its tufted heads of yellow saxifrageous flowers and its lanceolate toothed rather saw-edged foliage.

BOMAREA ACUTIFOLIA VAR. PUNCTATA.—An ornamental species of this interesting South American genus of climbers. It exhibits the usual features, with its parallel-veined leaves on twisted petioles and its flowers on pendulous umbels. The flowers are of a dull shade of red with lighter throat, which is, in the funnel-shaped perianth, heavily spotted with brown. The above two plants were shown by Mr. A. A. Dorrien Smith.

AZALEA VALENCIA.—A very hot-coloured (fiery red) variety. The petals of the flower are daintily waved and the exserted stamens lend charm to the flowers. Shown by Mr. Lionel de Rothschild, Exbury.

RHODODENDRON PILGRIM.—This variety bears exceedingly large, closely set trusses of large, individual flowers, each reminiscent of a gloxinia in appearance. They are open and well set on the truss, while they are of a rich pink in colour and full of substance. The foliage is also large and decorative and acts as a fine foil to the handsome trusses. Shown by Mr. Lionel de Rothschild.

ADIANTUM EMARGINATUM.—A most attractive species with leaflets almost semi-circular and something similar to a ginkgo leaf, but, of course, on a much smaller scale. With its black wiry stems and its dull green feathery foliage it should prove a fine ornamental plant for pot work. Shown by Mr. Amos Perry.

ROSE MRS. BEATTY.—An excellent seedling variety whose large, well formed and neat blooms are of a clear Maréchal Niel yellow, with the true Niel scent more pronounced. The growth is upright and the habit good, while the foliage is particularly attractive.

ROSE CECIL.—Another attractive seedling variety, whose single blooms are both handsome and of great size. In colour it is clear, bright yellow and represents quite a new break. These two new roses were both shown by Messrs. B. R. Cant, Colchester.

IRIS WATBRACT, A DAINTY HYBRID BETWEEN I. WATSONI AND I. BRACTEATA.

CARNATION DORCAS, SHOWN BY MR. C. ENGELMANN.

ORCHIDS.

FIRST-CLASS CERTIFICATES.

CATTLEYA WOLTERSIANA VAR. REX (Queen Mary × Rajah).—An elegant cattleya with unusually large flowers of uniform rose-purple colour, the labellum of dark purple, except for a narrow rose-tinted margin. Shown by Messrs. Cowan and Co., Southgate.

ODONTOGLOSSUM CRISPUM VAR. PREMIER DISRAELI.—A remarkably fine variety of this popular species. The spike bore ten large white flowers with the petals of grand formation and prettily fimbriated at the margin, while the labellum has a few reddish markings. Shown by Mr. J. J. Bolton, Claygate, Surrey.

CATTLEYA TITRIANÆ THE DELL PARK VAR. (Tityus × Trianæ).—A super hybrid which carried a couple of immense flowers of rosy mauve colour, the labellum rich purple, crimped at the margin, the throat veined with yellow, while the inner side of the lateral lobes is bright golden yellow. Shown by Baron Bruno Schröder, The Dell Park, Englefield Green, Surrey.

AWARDS OF MERIT.

CATTLEYA DR. M. LACROZE VAR. EXCELSIS (Octave Doin × Tityus).—This fine hybrid resembles a glorified C. Mendelii. The well formed flowers have the sepals and petals of light rose, the latter with a pretty venation of lighter tint over the whole area. The labellum has the front lobe of intense ruby crimson, the margin frilled and the throat yellow. Shown by Mr. R. Paterson, Stamperland House, Cathcart, Glasgow.

BRASSO-LÆLIO-CATTLEYA CALIGULA GATTON PARK VAR. (L.-C. callistoglossa × B.-C. Cliftonii).—A very pleasing flower of fine formation and soft mauve-pink colour, which extends evenly over the sepals and petals and round the margin of the labellum. The throat has a yellowish area near the apex of the column. Shown by Sir Jeremiah Colman, Bt., Gatton Park, Surrey.

MILTONIA PRINCESS ELIZABETH VAR. SUPERBA.—This is a hybrid of M. vexillaria var. G. D. Owen, and the well known character of a dark crimson blotch belonging to it has been transmitted to the seedling, but in a much more marked degree the labellum being covered over the greater part of its area with a dark crimson blotch, extended into spotting of similar colour. Shown by Messrs. Black and Flory, Slough.

CATTLEYA PRINCE SHIMADZU VAR. SUPERBA (Tityus × Hardyana).—The spike bore a couple of flowers of excellent shape; in fact, the petals overlap one another in front of the dorsal sepal. Of rosy mauve colour, the labellum ruby crimson and the throat yellow. Shown by Mr. Robert Paterson, Cathcart, Glasgow.

MILTONIA LUCIA (vexillaria × Princess Margaret).—A young plant of considerable promise. Sepals and petals of deep crimson, the broadly formed labellum rich purple with darker veining and bearing at its base a brownish mask and yellow crest. Shown by Mr. Robert Paterson, Cathcart, Glasgow.

LÆLIO-CATTLEYA CHLORIS VAR. VIVID (L. purpurata × L.-C. Gladiator).—A distinct hybrid which bore a spike of four large flowers resembling in general style an unusually fine form of L. purpurata, but with much wider segments. The petals are tinged with purple and veined with a darker colour, while the labellum is crimson-purple with a yellowish throat. Shown by Messrs. Sanders, St. Albans.

CATTLEYA PRINCE SHIMADZU VAR. DELICATA (Tityus × Hardyana).—A beautiful hybrid which bore a couple of large flowers of light blush colour, the expansive labellum well displayed and of golden yellow colour with purple mottling on the front area, the margin being prettily crisped. Shown by Mr. H. T. Pitt, Stamford Hill, N.

ODONTONIA PITTIÆ ROSSLYN VAR. (M. Blueana × O. Harryanum).—This attractive novelty bore a well set flower with the sepals and petals of port wine colour, showing some white mottling and with a narrow white margin. The labellum developed to marked degree, of dark purple colour, and with a yellowish crest at the base. Shown by Mr. H. T. Pitt, Stamford Hill, N.

ODONTOGLOSSUM TYNTESFIELD (parentage unknown).—The spike bore six large flowers with roundly formed segments, the petals marked with lilac-rose blotching and confluent spotting, the labellum white with reddish spots. Shown by Dr. Craven Moore, Victoria Park, Manchester.

CORRESPONDENCE

A WILD FLOWER PROTECTION ACT.

SIR,—There have been many complaints in the Press on the steady disappearance of our native flora from woodlands, hedgerows and meadows, and there are but few of us who cannot testify to the ruthless denudation of spots that but a few years ago were carpeted with spring flowers.

The relentless process of extirpation continues. The primroses, the cowslips, fritillaries, orchis, field and spotted, the ophrys, the ferns, in the neighbourhood of the populous areas are being decimated.

While it is true that some local authorities extend a measure of protection by prohibiting hawkers from selling rooted wild flowers, in the main such protection is negligible or non-existent. At this time of the year, the gipsy hawker, with a basket crammed with rooted wild flowers of the species I have indicated, the flowers almost certainly "socialised" from private property, is a common object of the suburbs and the outlying districts of our large towns. The householder buys them, maybe to go into the window box, the garden or what not, where, thanks to ignorance, inattention, lack of suitable soil, the grubbing of the ubiquitous cat, too much or too little sun, the plants die and are no more seen.

This sort of thing is deplorable; and as, in my opinion, the Royal Horticultural Society, by reason of its large membership its traditions and influence, is the best qualified body to suggest the lines of legislation to arrest this uncontrolled spirit of destruction, I have therefore been in communication with the council thereon, in the hope that an Act of Parliament to give a measure of protection to wild flowers on similar lines to that giving protection to wild birds, may materialise.

It would, doubtless, be desirable to extend similar safeguards to the rarer flora that stand no small risk of extinction owing to the enthusiastic and uncontrolled competition of genuine collectors and casual nature students; but as regards this point, legislation is one thing, effective legislation another.

I trust, however, that, if and when the subject of legislation arises, you and your readers will lend a hand in making constructive suggestions that may assist in the satisfactory solution of the problem.—CUTHBERT JAMES.

CODDLING PLANTS.

SIR,—I think we all read the Editorials in THE GARDEN. Sometimes we agree and sometimes we do not. In a recent issue the point was raised of "over coddling" plants. An instance of this may be of interest to others. Some six or seven years ago we formed a bed for Bocconia cordata. It was trenched down a good 3ft., manure, etc., added, but the only response was a puny growth about 18ins. high. The bed was mulched with good manure, and still no response. After four seasons of this we decided to scrap the bocconia and plant pampas grass. The bed was again well trenched, all *visible* bocconia picked out and the pampas grass planted. Result: bocconia 5ft. high! At the present time they are still fighting it out and the bocconia is well holding its own, with growths quite three times as high as when it was "on its own."—HIRED MAN.

COMBINATIONS FOR THE HERBACEOUS BORDER.

SIR,—I always read with great interest suggestions for combinations in the herbaceous border. Some years ago a friend recommended me to plant tulips among irises, and the effect has been greatly admired. Tulips such as Erguste, Rev. Ewbank, Bleu Aimable, are beautiful among the leaves of Pallida dalmatica. It is true that bulbs cannot be lifted annually, but I find it easy to renew them about every second year.

I have been very pleased with the letters recommending Zéphirine Drouhin, which has long been an occupant of my garden, and in conjunction with Clematis integrifolia Durandi is one of the successes which I have recorded. In addition to its many charms this rose has the value of being exceedingly easy to propagate by cuttings and very rapid in growth.—HEDGERLEY.

COLLAR ROT IN ASTERS.

SIR,—I have been greatly troubled with collar rot in the aster bed. This year seed was imported and sown in boxes, duly pinched out, hardened and planted in the open border early in November. The bed had previously been dug in the autumn and well limed. The previous crop had been mixed vegetables. Out of 200 asters six did not get collar rot. The other half of the bed had seed sown in the open ground and duly thinned. Sown early in November and when grown fat and sturdy—the suitable age for collar rot—we watered them once or twice a week with Condy's Fluid, about a dessertspoonful of crystals to 2 gals. of water. One or two plants have shown signs of the trouble, but otherwise the bed is splendid. I thought this might be of use to other collar rot sufferers and hope that other cures may be suggested.—M. P., *Christchurch, N.Z.*

THE NOMENCLATURE OF DWARF CONIFERS.

SIR,—I have just read Mr. Dallimore's interesting article upon "Dwarf Conifers" in your issue of April 17th, but in his reference to my book upon "Dwarf and Slow-Growing Conifers" I think he rather overrates the difficulties in procuring these forms. Of about 450 forms described I was actually able to procure about 300, and the next time Mr. Dallimore is in Ireland he can see about 200 of them flourishing on a slope beside the rock garden in Glasnevin, and I have about 160 small specimens, some of which are not in the Glasnevin collection, in my small garden in Surrey. No doubt a certain proportion of these are unobtainable at present, but there are over 100 forms in general cultivation which should be obtainable without difficulty. There is no dearth of dwarf forms in cultivation, but until the gardening public insists upon getting what it pays for I am afraid that most nurserymen will persist with their existing pernicious system of buying cheap Continental grafts and passing them on without verification.

In a first-class alpine nursery recently I saw a bed labelled "Juniperus Sanderi." This, to start with, is a false trade name for a variety of Cupressus obtusa, but the contents of the bed was even more extraordinary. There were but three plants of this cupressus among them, the remainder being a form of Cupressus thyoides and a form of Thuya occidentalis! At Vincent Square errors in naming are far too common.

Unfortunately, the mortality among these dwarf forms has been so great at Kew in recent years that it is difficult for the gardener to check what he is getting, and it is to be hoped that in the salubrious climate of the new National Pinetum in Kent a representative collection of these forms will be found for a permanent source of comparison for nurseryman and gardener.

May I in conclusion apologise to Mr. Dallimore for calling his attention to a few slight errors in the forms he describes, for the confusion is already so great that one hesitates to suffer it to increase? The form "Rheingold" is not, for instance, a form of Cupressus Lawsoniana, but of Thuya occidentalis, and, in the last paragraph, the form "etricoides," which he assigns to Thuya orientalis, is in reality a form of T. occidentalis, the two forms of T. orientalis with juvenile foliage being vars. juniperoides and Rosedalis. Finally, I hope he will discourage the trade name of "Juniperus hibernica compressa." The fastigiate juniper is not a native of Ireland (Elwes and Henry identify it with var. Suecica (Ait)), and therefore the tiny fastigiate juniper—J. communis compressa—has no connection with Ireland. It is suggested that a nurseryman who bought a fastigiate juniper had a brain wave which convinced him that as the fastigiate yew originated in Ireland the fastigiate juniper must come from the same source! and named it accordingly.—MURRAY HORNIBROOK.

NAMES OF EARLY POTATOES.

SIR,—May I crave a little space in your valuable paper to mention a few facts concerning varieties of potatoes which are synonymous and to substantiate my note which appeared in THE GARDEN of April 10th. The Potato Synonym Committee regard two potatoes as synonymous not only when they present precisely similar morphological characteristics as regard flower, foliage, habit of growth, colour of stem, stolon formation, size, shape and colour of tuber, but also when the two varieties possess identical physiological characteristics as exhibited by identity to maturity and resistance or susceptibility to wart disease.

Victory was tested at Ormskirk in 1919 and fell to wart disease; it was identical botanically to Duke of York, and classified as that type. I do not doubt for one moment but that the late Mr. Sim of Fyvie, Aberdeenshire, raised Victory, The Duke and others from seed, but if the botanical characteristics are in every respect the same as Duke of York, then surely the older variety must have pride of place.

In regard to yield and quality, Victory, as mentioned by Mr. Grant, Kincardineshire, in THE GARDEN, May 1st, page 273, would certainly be freer from mosaic, leaf-roll and other virus diseases and would give probably a heavier yield of tubers than the older strain until contaminated. Again, yield of tubers and quality are greatly influenced by change of soil and climatic conditions. When Duke of York is grown in Aberdeenshire, it produces splendid crops of potatoes of good cooking qualities; but when grown in the south the crop is generally poor.

If we take the Board of Agriculture returns for 1924 and examine the synonym list of potatoes, we find 1,701 names of potatoes. Is each variety, or so-called variety, different? I say no, emphatically no. Take three well known commercial varieties, say, Duke of York, British Queen and Up-to-date. Duke of York has thirty-one synonyms, British Queen has no fewer than seventy-five names to its credit, while Up-to-date had been baptised one hundred and seventy-five times.

Mr. Grant mentions reversion in potatoes as being due to the slipshod and careless selection of seed and to unscrupulous growers supplying seed of Duke of York when stocks of Victory run short. I have never found reversion in potatoes. Potatoes do not revert; once we get the type fixed it remains true to its type.

Deterioration is quite a different thing. Many varieties of potatoes deteriorate, due chiefly to the tremendous amount of constitutional diseases, such as leaf-roll and mosaic; but, although those diseases appear in the variety, it does not mean that the variety has reverted.—GEO. STUART, *Edinburgh.*

THE FLOWER GARDEN

HERBACEOUS PLANT SUPPORTS.

Early Staking is Essential.

MANY subjects in the herbaceous border will require artificial support by the time this article appears in print, and the earlier this is afforded the better it will be for the future welfare of the plants. There are various plant supports on the market, but at this early stage of plant growth I strongly advocate the use of short pea sticks placed around the clumps. They effectively fulfil their mission, and afford better protection than stakes or canes. The support, like the label, is very often a necessary evil, but the more it can be kept in the background the better. Nothing looks uglier than the orthodox green painted stake towering, at this early date, much higher than the plant. It is not the use but the abuse of this article I object to. There are districts where it is essential that strong stakes should be used; for instance, where the border is exposed to strong winds, but in many cases they are placed in position too soon, and one gets weary of their ugliness. Go round all plants as soon as they require supporting, as a heavy rain can do a deal of damage at this time of the year when growth is soft, placing short pea sticks around the clumps, always inclining the tops outwards to allow full expansion to each shoot. At the same time a certain amount of thinning out may be done where large clumps exist, leaving a few strong shoots which will make a better show when in flower than indifferent growth. As the plants progress use larger pea sticks or any of the advertised plant supports, but avoid showing too much of the support by allowing a few shoots to come through the supports, securing them by means of tar twine to the outside of the sticks. By the time the plants are ready for the final staking nothing will be seen of the earlier stakes, for they will be completely hidden by the foliage. The plants will display themselves to much better advantage than if one stake per clump had been used. How often one sees such plants as Erigeron Quakeress with a single cane thrust into the centre of the clump, a piece of string around it, and looking like a sack of corn tied in the middle rather than what ought to be a beautiful clump of flowers naturally displayed. Very often staking is not attempted until the flowering stage is nearly reached, and as the plants will have sprawled about during their growing season, they resent being bunched around a central stake for their final effort and look miserable and unhappy.—F. K.

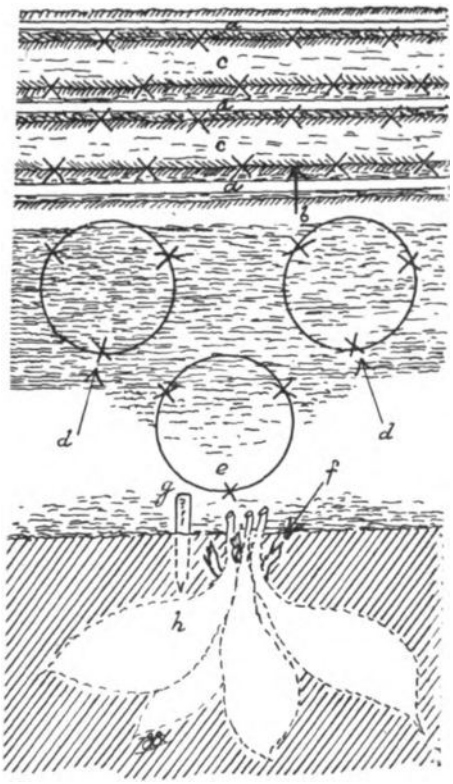
PLANTING DAHLIAS.

FOR a number of years the dahlia was not given the attention it deserved except by a few enthusiasts. Now, we seem to be, by common consent, in favour of dahlia-growing again and we have many gems to deal with. During the winter months it is as easy to store the dahlia roots as potato tubers. In spring, a little artificial heat will induce new shoots to grow which can be rooted as easily as those of the zonal pelargonium, and after the shoots are so dealt with the old tubers are still available for planting out in the borders. Of course, as frosts kill the old plants in the autumn, they will also kill the young ones in late spring. In southern counties it is, generally, safe to plant out in open borders about the second week in June, but in the north it is unwise to risk full exposure until nearer the end of the month.

In the absence of frosts excessive cold stops growth and the check delays the flowering by a fortnight or so. Some protection should be afforded at night until the last week in June unless the weather is very mild. The dahlia is a gross feeding plant and does not succeed satisfactorily in a naturally poor and unmanured soil. The manure applied should be well rotted and, if convenient, it should be mixed with the soil several weeks prior to the date of planting. In cases where this timely manuring has not been done, apply a liberal dressing now. If organic manures are not available, use half-rotted leaf-soil, also liberally.

Both young plants and old growing tubers, especially the latter, require to be planted deeply, so it is most beneficial to mix the manure with the soil about 1ft. below the surface. It should not come into direct contact with the tubers but with the new fibrous roots.

Plant according to height; those growing 3ft. high 3ft. apart, and so on. Do not



a a a Narrow path between beds b and c c; group planting is shown at d d and e—crosses represent plants; f, young shoots coming through soil; g, labels clear of plants, not driven into tubers h.

tread unduly on the soil after planting. Place three stakes to each plant and, later, a few branching sticks as required.—G. G.

SWEET PEAS AND GREEN FLY.

FROM late spring until well into the summer green fly or aphis are apt to attack sweet peas, particularly in seasons favourable to their rapid increase. Most amateur growers pay little heed to them and where sweet peas are grown naturally and left to form a thick hedge or clumps they will do little harm. But in the case of the keen exhibitor, practising the "one-stem" or "cordon" system of culture, green fly may completely upset his plans. If unchecked, the aphides cluster on the slender growing tips of the plants, poisoning them and sucking the sap juices which should normally assist in their development. The result is, at the best, stunted growth and, at the worst, a curious twisting up and crinkling of the haulm, leaves and stems produced immediately afterwards. Usually, the blooms are misshapen on short, twisted stems, and sometimes even the colour is changed. Varieties such as Mrs. Cuthbertson, Annie Ireland, Youth and, indeed, all picotees and most bicolors, assume a mottled, streaky appearance. This "running" of the colour is the result of aphis puncturing and sucking sap from the tiny flower-buds. Inexperienced growers often mistakenly imagine such plants are "rogues," or, perhaps, are afflicted with the mysterious disease called "streak," that bogey-man of the sweet pea enthusiast which apparently no one has yet succeeded in laying by the heels. Aphides, under favourable circumstances, multiply at a most extraordinary rate, but birds, thunder showers, ladybirds and cold spells of weather all do their part in keeping the hordes somewhere within bounds. The only safe method I know to eradicate them out of doors from sweet peas is to spray with a good insecticide, either home-made or one of the many excellent preparations on the market similar to the well known "Abol." Whatever insecticide is used, the directions given by the makers should be implicitly followed. To make doubly sure try it on a few plants at first and notice the effect it has, both on the aphides and the plants themselves. If the foliage "spots" or "burns" within twenty-four hours, either the preparation is too strong or otherwise unsuitable in some other way. Apply with a "mist" nozzle in the evening, paying particular attention to the growing tips and under sides of the leaves. Early the next morning syringe the plants again with pure, soft water to clean off the insecticide, which sometimes is rather sticky and liable to block up the pores of the leaves. A second application in a few days may be necessary to destroy all aphides completely. The main point is to syringe before the fly has time to do serious damage.—C. H. A. S.

CLEAN ROSES.

The Importance of Spraying.

READERS who are fortunate enough to have large open gardens find that their plants remain clean and vigorous in all normal years, but the man who is "cribbed, cabined and confined" has not the same luck. Even if aphides do not appear and continue to appear in colonies, there is always a close, dusty atmosphere which coats the foliage with a film of dust, making it appear sickly and forlorn when the weather is dry and trying. Such growers must resign themselves to the necessity for continual spraying, not frequently, but fairly regularly. Provided that the best kind of spray is used, then the bushes will remain perfectly clean, and such clean roses keep naturally vigorous thereafter. Spraying, too, keeps aphides away and other pests seldom get a chance to become virulent.

Although the day for making elaborate rose washes at home is past, I would emphasise the efficacy of plain soap solutions applied tepid. Soap of any kind may be used. Soft soap is often too caustic, however, and I pin my faith to what are called disinfectant hard soaps (like cyllin, carbolic, naptha, etc.) and the horticultural nicotine soap. The solutions made from hard soap can easily be made by boiling the soap in a little water in the copper. For spraying 2 oz. per gallon is a fair average. Two pounds of soap boiled in a gallon of water till dissolved makes a concentrate which can be used at the rate of 1 pint poured into 2 gallons of water. As indicated, I prefer using tepid water, *i.e.*, water not exceeding 90° F.—LANARKSHIRE.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

IN THE FLOWER GARDEN.

Wallflowers.—If not already done, seeds of these beautiful spring-flowering plants should be sown. Late sowing never produces such fine plants as those raised earlier.

Hardy Primulas.—These have been making an unusually fine show, and as the majority are best treated as biennials, it behoves the grower to save a little seed of every kind each year. Home-saved seed of hardy primulas always germinates more freely than seeds from other sources, and if sown directly it is ripe, plenty of plants will be secured. Prick them off in a shady part of the garden, and when they die down transfer them to their flowering quarters.

Climbing Plants.—Among the numerous climbers will be found the clematis, solanums, wistarias, etc., and it is advisable to train the shoots at frequent intervals before they become a hopeless mass. Where they are growing on stumps of old trees they may develop unmolested.

THE KITCHEN GARDEN.

Lettuce.—In hot dry weather it is often difficult to keep up a supply, but a good method is to transplant a reliable cabbage variety in frames (discarding the lights) placed near the water tank. A layer of rotten manure should be laid in the bottom of the frame and then a few inches of old potting soil and, after a thorough watering, the plants should be set out a few inches apart. Shade them for a week or so when the sun is bright and keep the soil moist. A pinch of seed should be sown about every ten days.

Brussels Sprouts.—The main crop should be planted in a fairly rich soil which has been deeply dug and then made firm by treading. The plants should be set out 30ins. apart and the roots must be afforded plenty of water until they take possession of the soil. Future treatment consists of a free use of the hoe and an occasional dusting of soot.

Potatoes.—Continue to hoe or lightly fork between the rows of late potatoes. Earthing-up should begin directly the haulm is sufficiently advanced and when the soil is more or less moist. Avoid making sharp ridges that would drain off the rain.

Leeks.—Some of the seedlings will be large enough to transplant either in a trench or in rows, The former is made similar to a pea trench and the plants placed in a double line about 15ins. apart. They may also be planted with a dibber. This is pushed well down into the soil, and the plants are set deeply in the hole with a little soil pressed lightly around the roots. As the plants grow the hole should be filled during the process of hoeing. Water will be needed if the soil is dry. Leeks enjoy a rich soil, but good quality roots may be had from any ordinary garden. When grown in lines they should be about 1ft. apart.

Swedes.—These are highly appreciated in many houses, and now is a good time to sow a few lines about 18ins. apart. Where turnips are not a satisfactory crop, swedes are strongly recommended, and when the seedlings are large enough they must be thinned to 9ins. The turnip fly must be watched for, and as a preventive an occasional dusting of soot should be given.

VEGETABLES UNDER GLASS.

Cucumbers.—Many plants will be in full bearing, and in consequence ought to be assisted with a light sprinkling of artificial manure or top-dressed with loam. The golden rule with special manures is a little and often, and always on the light side. Plants growing in greenhouses or frames should receive constant attention in regard to stopping, and each lateral shoot ought to be pinched at the first or second leaf beyond the fruit. A more or less moist atmosphere is needed, and on bright days the house is syringed round about 8 a.m. and again at 4 p.m., when all ventilators are closed. White fly is often troublesome, and directly this pest is seen, the house or frame must be vaporised with a fumigant especially manufactured for this particular fly. It is very effective if repeated for a time at intervals of ten days. A few seeds can be sown for a late supply of cucumbers, Everyday and Telegraph being useful varieties.

Melons.—These require much the same treatment as cucumbers up to a certain point, whether cultivated in greenhouses or frames The point is reached when the female flowers open on the lateral growths. Three to six melons are enough for one plant, and these should be started at near the same time as possible, otherwise one or two fruits will take the lead, and the remainder fail to develop. At this season the main crop of melons will be approaching the flowering stage, and it will be necessary for the grower to watch the plants. When the requisite number of female flowers are open, each one must be fertilised with the pollen from a male bloom, these being produced in quantity. During this period the atmosphere is kept on the dry side, and more air admitted. When the fruits are set and begin to swell freely, the roots are fed with weak liquid manure, soot water and artificial manure. Keep all lateral growths pinched, and if the main stem exhibits signs of decay close to the soil, apply powdered charcoal liberally and frequently until the trouble disappears. While the roots are in a state of activity keep them well supplied with water. Use the syringe freely until the ripening stage is apparent, and admit air whenever the weather is favourable for opening the ventilators.

Tomatoes.—Little difficulty should be experienced in growing a full crop of these popular fruits, and as a lad I was assured by my chief that no insect pest ever troubled tomato plants. Alas now this is not true, and that awful pest, white fly, is preventing tomatoes being grown in some private gardens, at any rate under glass. No half-hearted measures are effective, and if the greenhouses are situated in close proximity to flower or vegetable borders, the struggle is almost hopeless. I have in a large measure succeeded by frequent fumigations in the early stages of the attack, by feeding the roots with liquid manure, and applying the hose pipe daily when the weather is bright. Probably many readers of THE GARDEN could furnish details of their treatment, taking into consideration the position of the greenhouse, because white fly is found in abundance on many flowers and vegetables grown in the open ground here in Gloucestershire and Monmouthshire. It will be interesting to note if the hard winter has had any effect on this pest in the open. Tomatoes growing under glass whether in large pots or planted out must be kept moist at the roots, and the best stimulant is a manure containing a fair percentage of potash, otherwise the fruits will be deficient in colour and hard near the stalk. Remove all side growths as they appear.

PEACHES AND NECTARINES UNDER GLASS.

In these days it is questionable whether these fruits are forced to any great extent, the majority being grown more or less naturally with perhaps a little fire heat during the early stages of growth. Such trees will now be in an active state, the fruits will be swelling while the new shoots are making headway. Guard against overcropping, and where the fruits are numerous a few ought to be removed, leaving about three to 2 sq. ft. of the tree. The growths should also be reduced to prevent overcrowding, otherwise the necessary light and air will not penetrate the tree. Leave just enough new shoots to furnish fruiting wood for next year. It is essential at this period to keep the foliage free from red spider, so the syringe or hose pipe must be used with force daily, but such work should be carried out sufficiently early for the leaves to dry before sunset. Never allow the roots to become dry, and if the trees are rather stunted a sprinkling of approved fruit manure will be beneficial. Old soot scattered over the border will be an advantage, and help to promote clean healthy green foliage. Where the trees show signs of shot hole fungus, or silver leaf disease, apply Wood's Veltha Powder 30z. or 40z. to the square yard. Lightly fork in so that it reaches the roots. I have proved this remedy to be most effective, especially for trees with a yellowish sickly appearance.

Chepstow. T. W. BRISCOE.

FOR NORTHERN GARDENS.

THE KITCHEN GARDEN.

About this period falls due the planting of main-crop and late cauliflower and cabbage, broccoli, savoys and kales for late autumn and winter use. Asparagus, Favourite Kale and sprouting broccoli for use early in spring of the following year. It pays in the end to give these borecoles a well prepared and manured site to induce a free summer's growth, so necessary to the formation of a productive plant.

Allow at least 2ft. apart each way. Firm planting is essential, and water to give the plants a start in dry weather.

Leeks sown under glass for an early crop will be fit to plant out now. Draw deep drills 1ft. asunder, spacing the plants 9ins. apart in the rows. Push the dibber well down, insert the plants as deep as the base of the leaves, merely cover the roots with soil or fill the hole with water, making no attempt to firm these as one would a cabbage plant.

The subsequent hoeing of the ground and filling in of the drills will add to the length of "blanch."

Chicory.—Where this excellent succulent is appreciated for its various uses, seed may be sown now. Select ground well dug and not recently manured, sow the seed in drills 1in. apart and 1in. deep, watering the drills before sowing if the soil is dry, later thinning out the plants to 9ins. in the rows.

GENERAL WORK TO BE DONE IN THE GARDEN.

In the pressure of work consequent to the planting out of the flower and vegetable gardens, other essential jobs must be attended to for the good of the crops.

The principal of these is the staking of main-crop peas. Previous to staking, give a sprinkling of superphosphate to the young plants—about 2 oz. per yard run—and draw a little soil up to the plants on each side of the row.

Staking should be done before the young plants show any signs of falling over.

Lines of seedling peas of late varieties are less prone to attacks of birds and slugs than early varieties, but any evidence of such attacks should be countered with dustings of soot or lime.

A light dressing of nitrate of soda will help to give the plants a start and carry the plants beyond the attacks of pea weevil.

Pick the pods frequently from early varieties, as they soon lose flavour and tenderness, promote seed development and unnecessary absorption of nourishment, to the curtailment of culinary supplies.

In the absence of rain, afford copious supplies of water; but even this will avail little in such a crisis if the previous work of trenching and manuring has been skimped.

Broad beans, if showing a fair amount of blossom, may have the tips pinched out, whether black fly be in evidence or not, to concentrate all the energies of the plant in the formation of pods. Draw soil up to the plants and support the haulm by running strings on each side of the rows. Spray with paraffin emulsion for attacks of black fly.

The ground between rows of main-crop potatoes should be well broken up for the good of the plants and to facilitate the operation of "earthing up."

If only organic manure has been employed up to this period, the plants will benefit from a dressing of sulphate of potash, 2 oz. per lineal yard, applied before earthing up. Do not draw up too much soil, for if 6ins. has been found a suitable height, more will not increase the yield of tubers.

In completing the work, leave the ridges rather flat, to absorb rather than gather moisture, which might encourage the spread of disease.

Keep the cultivator going as steadily as opportunity will permit between the rows of turnips, carrots, onions and recently planted vegetables.

In dry weather this is the best means of economising the water supply. But in a drought artificial watering has to be resorted to, especially in the case of vegetables, the root system of which is undeveloped and consequently unable to supply the plant with the amount of water required, and to crops such as lettuce which have extensive and succulent leaf surface.

Doune, Perthshire. W. MCCARRELL.

GARDEN SUNDRIES AT CHELSEA

GARDEN ORNAMENTS.

THERE are many corners in the garden which can be made beautiful by adding a well chosen ornament. A sundial in the middle of a sunk garden, a piece of garden statuary at the end of a vista, or a row of stone vases along a terrace all lend character to their surroundings. Although natural stone and lead are claimed to be the best kind of materials from which such ornaments can be made, there are many types of artificial stone ornaments now on the market which, besides being far cheaper, look attractive, weather well and do not suffer from the effects of frost. The Bromsgrove Guild, Limited, were exhibiting artificial stone ornaments made from a material called "Castone." These ornaments are similar in colour and surface to Portland stone, and they are said to stand all climatic conditions. The vases made by this firm were most artistic in design.

Messrs. Sanders and Co., Messrs. Gaze, and Messrs. Pulham, all exhibited a great variety of garden ornaments, both in lead and stone. The bird-nesting boxes exhibited by Messrs. H. Moorton are scientifically constructed and recommended by the Royal Society for the Protection of Birds. Several small lead figures on the stand of Messrs. W. Wood were much admired.

GARDEN FURNITURE.

No garden is complete without some article of garden furniture. Provided this is of the right style to suit the particular garden, it not only adds to the beauty of its surroundings, but enables the owner to appreciate more fully the charm of his flowers and trees. Design, durability and construction should be considered when purchasing any kind of furniture. Few types have more to recommend them than those made of teak. Chairs and tables of this material last for an indefinite number of years, require no painting and always look well. The Hughes Bolckow Shipbreaking Co. make all kinds of teak wood furniture from old battleships. Excellent workmanship is put into all their products and the seats they were exhibiting at the Show, made from H.M.S. Lion were of particularly good design. Messrs. Castle's old Man o' War teak furniture, which has a wide reputation, was also on show. Benches and seats of natural stone look most attractive in an old-world garden and harmonise well with any colour scheme. They should be simple, and, preferably, made of Portland or Bath stone, such as those made by the Horsecombe Quarries. A cheaper kind of furniture which is nevertheless most satisfactory, is made from well seasoned deal and enamelled white. This needs repainting annually and an occasional scrubbing. A painted wooden seat made by the Padworth Industries has a useful flat table fixed at either end.

Portable chairs are becoming more and more popular as their variety and restfulness increase. A folding portable chair exhibited by Messrs. T. J. Syer is particularly useful, as it is made with a detachable washable seat and back. Garden chairs of all shapes and sizes, made from cane and soft pliable sea grass, were shown by The Paramount Furnishing Co., and a couch swing hammock, exhibited by Messrs. Piggot Bros., would be ideal for a loggia. One of the latest inventions was a combined dinner wagon and table shown by Messrs. Harrods, while every article of garden furniture made by the disabled soldiers at Lord Roberts' Memorial Workshops was of the best materials and showed great skill in the making.

INSECTICIDES AND FERTILISERS.

The progress of science in horticultural matters of all kinds was fully evidenced at Chelsea, especially in connection with plant foods and with sprays for combating insect and fungoid pests. New fertilisers and insecticides were on show, and one can rely on the purity and efficacy of these. A new and complete garden fertiliser which acts as a tonic for flowers, fruit and vegetables was displayed by Messrs. Price and Co. From its analysis it compares very favourably with other fertilisers on the market, and, as it is in a form which is not readily washed out of the soil, it should prove most economical in use. The advantages of a dressing of lawn sand were exhibited by Messrs. J. Fison. On this stand were two separate boxes containing weeds found in grass; one had been dressed three days previously with lawn sand, the other had received no dressing. The weeds which had received the application were quite dead. Another useful material seen on this stand was Tarbol, which is a most effective remedy for leather-jackets and worms on lawns.

In a garden where there are animals or chickens, a poisonous weed-killer cannot be used. It is for this reason that Messrs. Abol, as well as a number of other firms, are producing a weed-killer which, although it is non-arsenical, can be relied upon to kill weeds and moss on paths. When putting down at-killer, the difficulty of poisoning domestic animals again crops up. This firm is, therefore, making a new rat-killer, known as "Nomorats," which is neither poisonous to other animals nor yet a virus. The rats do not die in the holes, but come out into the open to die.

Messrs. Robinson's Multiple Slug-killer was another very useful material on show. Messrs. Adco were exhibiting quantities of garden refuse which had been converted into synthetic farmyard manure by the addition of their preparation known as Adco.

Insecticides and weedicides for every purpose, made by the well known firm of Messrs. Cooper, McDougall and Robertson, were an interesting feature in the Sundries Avenue. Messrs. Wakeley's celebrated hop manure was seen on their stand; and the beneficial effects of Key fertilisers on lawns were demonstrated by the Key Fertiliser Company. Messrs. Corry had an exhibit of insecticides of all kinds and their famous sundries, including white-fly fumigant.

LAWN MOWERS.

As usual, that portion of the main avenue devoted to lawn machines and tools aroused considerable interest among the visiting public. Messrs. Alex Shanks and Sons were responsible for a well grouped collection of practically all types of their popular lawn mowers and rollers. Both hand and power machines were shown, and the exhibit aroused much interest. At the stand of Messrs. Charles Pugh, Limited, a fine range of the well known "Atco" motor mowers in all sizes, from 14ins. to 36ins., was to be seen. Two useful appliances which were also demonstrated at this stand were the "Atco" turf Cultivator and the "Atco" turf renovating tool.

Messrs. Ransomes, Sims and Jefferies displayed a general selection of their various types of hand and power machines, together with the popular Ransomes edge trimmer, in an attractive manner.

Several of the many up-to-date features of the aptly named "J.P. Super" lawn mower were shown in a very practical manner by its manufacturers. Cut sections of the more intricate portions of the mechanism enabled the visitor to see at a glance the actual inner workings of the machine. A new feature was noticed in a motor machine of 24ins. cut which incorporates all the usual features of the "J.P." hand machine. Messrs. Thomas Green and Sons exhibited a fine collection of machines of all sizes, which included the well known side wheel type of "New Century" machine. An interesting feature on this stand was a very simple, but nevertheless effective, automatic machine for cleaning soiled tennis balls. This appliance supplies a long-felt want and should prove very popular. The well known "Dennis" motor mower was displayed in a very attractive manner by Messrs. Dennis Brothers, and the general interest which was created by this exhibit speaks very highly for the all-round excellence and popularity of the machine itself. The Godiva Engineering Company were responsible for an interesting display of various machines and appliances. At the stand of Messrs. Lloyd and Co. of Letchworth were to be found many useful items which included lawn sweepers, sprinklers, mowing machines, etc.

TOOLS AND SUNDRIES.

One of the finest exhibits in the Sundries Avenue was undoubtedly that of Messrs. Thomas Gunn, Limited, who were responsible for a really well displayed collection of many useful garden implements. These were in wide variety and included a good selection of hand and power mowing machines.

The firm of H. Pattisson were again showing their well known "Sarel" spiked lawn roller, together with the pony boots for which they have become famous. The Pattisson Graduator Distributor for the successful sowing or top-dressing of lawns was also featured.

The renowned "Acme" labels were a prominent feature on the stand of Messrs. John Pinches. Many forms of flower supports and exhibiting appliances were also successfully shown.

Major Walker displayed and demonstrated the advantages of his fruit tree protectors and transferable fruit cages, in an exceedingly practical manner.

Both the Wilkinson Sword Company and also Mr. C. A. Jardine were responsible for fine exhibits of secateurs and other keen-edged horticultural tools.

Messrs. House and Garden Sundries exhibited many useful little horticultural aids, including the "Everyman" garden netting and screen supports.

The "Rival" plant stakes were shown to advantage by Mr. H. J. Greenwood. These could be seen in practical use as supports for various flowers which were displayed in pots for this purpose.

On the stand of Messrs. Joh. Hansen much interest was evoked by practical demonstrations of the "Little Wonder" hedge cutting machine. A new motor cultivator, known as "The Bolens" and of American origin, was also on view here.

The splendid articles exhibited on the stand occupied by St. Dunstan's was typical of the efforts which are being made to provide blinded ex-Service men with work of a practical nature. Garden nets, hammocks, tennis nets and surrounds of really excellent quality were to be seen, and it is to be hoped that this exhibit received the support it deserved.

SPRAYING AND SPRINKLING APPARATUS.

Such a large number of exhibitors were displaying spraying and sprinkling apparatus of all kinds that an attempt to give a detailed account of each would be impossible in the space at our disposal, and this subject will be dealt with more fully at a later date. Many fine types of hand syringes, knapsack sprayers, pneumatic portable and wheel machines were to be seen on all sides, while the various lance and hose extensions which were to be obtained for use with most types were, generally speaking, efficient and simple. From the various improvements which were to be seen it is evident that many progressive

manufacturers are making rapid strides in the evolution of the perfect spraying machine.

Messrs. Robinson Brothers.—Comprehensive selection of all types of up-to-date spraying machinery.

Messrs. Martineau and Smith.—A fine display of all types of spraying apparatus, including many small portable pneumatic machines.

Messrs. Stonehouse Works Company.—Among many other interesting features was to be seen the new "Telesco" telescopic syringe, which can be used for many purposes.

Messrs. Abol, Limited.—Fine collection of "Abol" syringes and spraying specialities of all kinds.

Messrs. Four Oaks Company.—Well displayed selection of numerous machines for use in the garden, orchard or farm.

Messrs. Con-o-Mist.—Small pneumatic machines which are very convenient to handle were here shown to advantage.

Messrs. Holder Harriden.—Large display of all types of spraying machinery, ranging in capacity from 2 pints to 50 gallons.

Messrs. Eclipse Spraying Company.—Very practical demonstrations of the many uses to which the new "Eclipse" sprayer can be adapted were being continually given by thi progressive firm.

Messrs. Carter and Co. devoted considerable attention to demonstrations of a new sprayer, the "Ideal," which appears to very very simple and efficient in working.

The exhibit of the B.O.I.L. Company was once again the centre of considerable interest. The various methods of overhead irrigation advocated by this firm were ideally demonstrated under extremely difficult conditions.

LIST OF AWARDS

CHALLENGE CUPS.

Sherwood Memorial Cup, for the most meritorious group: To Messrs. Sutton and Sons.

"Daily Graphic" Cup, for the best rock garden: To Messrs. Pulham and Son.

Cain Cup, for the best exhibit by an amateur: To Sir Jeremiah Colman, Bt. (gardener, J. Collier).

Orchid Challenge Cup, for the best exhibit of orchids by an amateur: To Mr. H. T. Pitt.

Sutton Silver Cup, for the best amateur exhibit of vegetables: To Baron Bruno Schröder (gardener, E. J. Henderson).

Fruit and Vegetables.—Gold medal: To the Hon. Vicary Gibbs (gardener, E. Beckett). Silver-gilt Banksian medals: To Baron B. Schröder (gardener, E. J. Henderson); Messrs. Sutton and Sons. Knightian medal: To the Guild of Blind Gardeners. Silver-gilt Hogg medals: To Messrs. G. Bunyard and Co., Limited; Laxton Bros. Silver Hogg medal: To Messrs. Rivers and Sons, Limited.

Irises.—Gold medal: To Messrs. G. Bunyard and Co., Limited. Silver cup: To Messrs. the Orpington Nurseries Co. Silver-gilt Banksian medals: To Messrs. Barr and Sons; De Goede Bros. Silver Banksian medal: To Mr. G. G. Whitelegg.

Shrubs.—Silver cup: To Messrs. J. Waterer, Sons and Crisp, Limited; Hillier and Sons. Silver-gilt Flora medals: To Messrs. R. and G. Cuthbert; M. Koster and Sons; R. C. Notcutt. Silver-gilt Banksian medals: To Messrs. G. Reuthe; Donard Nursery Co.; W. Fromow and Sons; L. R. Russell, Limited; Hosea Waterer; W. Cutbush and Son; A. Charlton and Sons; R. and G. Cuthbert. Silver Flora medals: To Messrs. Hosea Waterer; Hollamby's Nurseries; J. Cheal and Sons, Limited. Silver Banksian medals: To Messrs. T. Lewis; Robert Green, Limited; John Klinkert. Flora medal: To Messrs. Hollamby's Nurseries. Banksian medals: To Messrs. M. Koster and Sons; R. Gill and Son.

Orchids (Amateur exhibits).—Silver cup: To Sir J. Colman, Bt. (gardener, J. Collier). Silver-gilt Flora medal: To Mr. H. T. Pitt.

Orchids (Trade exhibits).—Gold medals: To Messrs. Charlesworth and Co.; J. and A. McBean. Silver cups: To Messrs. Sanders; Cowan and Co. Silver-gilt Flora medals: To Messrs. Armstrong and Brown; Stuart Low and Co. Silver-gilt Banksian medals: To Messrs. Black and Flory; J. Cypher and Sons. Silver Flora medal: To Messrs. Mansell and Hatcher. Silver Banksian medal: To Messrs. Sutton Bros. Flora medal: Mr. H. Dixon.

Rock Gardens.—Gold medal: To Messrs. Pulham and Son: Silver cups: To Captain B. H. B. Symons-Jeune; Mr. G. G. Whitelegg. Silver-gilt Flora medal: To Messrs. H. Brook; Clarence Elliott, Limited; Hodsons, Limited. Flora medal: To Messrs. Gavin Jones.

Sweet Peas.—Silver cups: To Messrs. R. Bolton and Son; Dobbie and Co., Limited.

Carnations.—Silver cups: To Messrs. Allwood Bros.; C. Engelmann, Limited. Silver-gilt Banksian medal: To Sir Wm. E. Cain, Bt. (gardener, C. Moore). Silver Banksian medal: To Mr. J. Douglas. Banksian medal: To Messrs. Stuart Low and Co.

Tulips.—Silver-gilt Banksian medal: To Messrs. Dobbie and Co., Limited. Silver Flora medal: To Mr. H. G. Longford. Flora Medal: To Messrs. Barr and Sons. Banksian medal: To Messrs. E. Paul and Co.

Roses.—Gold medal: To Messrs. B. R. Cant and Sons. Silver cup: To Mr. E. J. Hicks. Silver-gilt Flora medal: Messrs. Chaplin Bros, Limited. Silver-gilt Banksian medal: To Messrs. A. J. and C. Allen; G. Prince. Silver Banksian medal: To Messrs. F. Cant and Co. Banksian medals: To Messrs. E. Paul and Co.; J. H. Pemberton.

Formal Gardens.—Gold medal: To Messrs. R. Wallace and Co., Limited. Silver cups: To Messrs. Bakers, Limited; Vernon Bros. Silver-gilt Flora medals: To Messrs. J. Carter and Co.; J. Cheal and Son, Limited; W. H. Gaze and Sons, Limited. Silver-gilt Banksian medals: To Messrs. R. Neal and Son; Wm. Wood and Son, Limited. Silver Flora medals: To Mr. E. Dixon; Mr. James McDonald.

Alpines.—Silver cup: Messrs. M. Prichard and Sons. Silver-gilt Lindley medal: To Lady Aberconway and the Hon. H. D. McLaren. Silver-gilt Flora medals: To Messrs. Oliver and Hunter; R. Tucker and Sons. Silver-gilt Banksian medals: To Messrs. Clarence Elliott; Bakers, Limited; J. Waterer, Sons and Crisp, Limited. Silver Flora medals: To Messrs. Maxwell and Beale; Bowell and Skarratt; F. G. Wood. Silver Banksian medals; To W. E. Th. Ingwersen; Carter Page and Co. Flora medals: To Messrs. R. V. Rogers; W. H. Rogers and Son, Limited; J. Cheal and Sons, Limited; H. Hemsley; Jeans and Trowbridge; Gavin Jones; G. Reuthe; W. Wells, Junr. Banksian medals: To Messrs. Central Garden Supplies; Hodsons, Limited; Miss Hopkins.

Mixed Groups.—Gold medals: To Messrs. R. Wallace and Co., Limited; Sutton and Sons. Silver cups: To Messrs. L. R. Russell, Limited; H. J. Jones; Blackmore and Langdon; G. Jackman and Son; James Carter and Co; Amos Perry. Silver-gilt Flora medals: To Messrs. Wm. Cutbush and Son; M. Prichard and Sons; Bees, Limited; Amos Perry. Silver-gilt Banksian medals: To Messrs. Stuart Low and Co.; W. Artindale and Son; Carter Page and Co.; G. R. Downer. Silver Flora medals: To Messrs. Storrie and Storrie; Blackmore and Langdon; Toogood and Sons, Limited; R. H. Bath, Limited; Bakers, Limited; W. H. Walters; J. Waterer, Sons and Crisp, Limited. Silver Banksian medals: To Mr. H. B. Brandt; Studley College; Messrs. Golfrey and Son; A. Dawkins; Watkins and Simpson, Limited; G. H. Dalrymple; J. Douglas; Wilson and Agar; Hewitt and Co.; Yokohama Nursery Co. Flora medals: To Messrs. J. Peed and Son; S. Smith; Jarman and Co.; G. A. Miller; F. Gifford; J. C. Allgrove; H. N. Ellison. Banksian medals: To Messrs. E. Webb and Sons, Limited; R. J. Case; Chalk Hill Nurseries; B. Ladhams, Limited; Reamsbottom and Co. (two); Wm. Yandell.

Scientific exhibits.—Silver-gilt Grenfell medals: To the East Malling Research Station for exhibit of fruit on different stocks. To the Royal Botanic Garden, Edinburgh, for herbarium specimens of new Chinese plants. To Dr. G. H. Rodman, for photomicrographs of plant hairs. Silver Grenfell medals: To the Rothamsted Experimental Station for illustrations of research on horticultural crops. To the Royal Botanic Gardens, Kew, for herbarium specimens of new Chinese plants. Grenfell medal: To the Experimental and Research Station, Cheshunt, for exhibit of greenhouse pests.

Paintings.—Silver-gilt Grenfell medal: To Miss W. M. A. Brooke, for paintings and drawings of flowers and insects. Silver Grenfell medals: To Mrs. N. Blacklock, for water-colour paintings of flowers; Mrs. Edith Fisher, for water-colour paintings of gardens; Miss E. Savory, for pictures of flowers; Miss J. N. Williams, for paintings of gardens and flowers.

In the report of the exhibits of Trees and Shrubs on show at Chelsea, we unfortunately omitted to make reference to the fine display of clipped golden yews from Knaphill Nurseries, Woking, where for so many years the late Mr. Anthony Waterer made topiary his personal hobby. This exhibit was full of interest to those who are enthusiastic formal gardeners.

REVERSION OR NETTLE-HEAD IN BLACK CURRANTS.

THIS is one of the most serious troubles met with in the cultivation of the black currant. It is a much more modern one than "big bud," but it is not by any means certain that it will not be as serious—if not more so—than the big bud. The name has been suggested by the curious appearance of the foliage. The latter name is best suited to it, because it is well known that the bushes do not actually revert to the wild type, and nettle-head is a very apt description. Hence it is not very difficult to recognise a badly affected bush, though slightly attacked branches are not easy to recognise. Another way, and perhaps a surer one, of recognising affected plants is by means of the flower buds. On reverted bushes these carry more "bloom" (due to hairs) than is found on the flower buds of healthy plants.

This is, therefore, the means generally adopted by those who are keen on keeping their stock clean. Any plants showing signs of reversion are then either destroyed or marked for removal after the crop has been gathered. A badly reverted bush will cease to bear, but it often happens that the plants go branch by branch.

Methods of control are difficult. Practically there are only two at present. One is to "rogue" every plant showing signs of attack, and the other to propagate from clean stock. If care in propagating were consistently followed up by every grower, it is possible that the trouble would at any rate be kept within bounds, especially if followed by good cultivation.

With regard to propagation, it is recommended by a high authority on the subject that propagation from healthy green cuttings, instead of the usual one by dormant shoots, will prove almost, if not entirely, successful.

In addition to these pests the black currant is subject to several others, notably aphis. The first signs of aphis attack are noticed by the bunching of the young top leaves. This usually appears in May and goes on through June if not combated. The result in such a case is sometimes serious.

The currant lettuce aphis is capable of doing a lot of damage—in some seasons much more so than in others. Like most aphides it feeds on the under sides of the leaves, where it deposits a sticky secretion. The bushes should be sprayed directly the aphis is seen, with a soft soap and nicotine wash or any efficient proprietary spray mixture. Possibly the best way is to dip the ends of the shoots into the mixture. By this means one is certain that all the pests have been immersed.

This by no means exhausts the number of pests and diseases liable to attack black currants; but the others, such as the Clear Wing moth, saw-fly and red spider, and the diseases leaf spot and rust, are not so serious.

I am afraid that the foregoing remarks give a somewhat pessimistic tone to the culture of black currants, but it is not intended to do so; rather it is meant as an appeal to growers to be careful.

A. J. Cobb.

FEEDING & WATERING GLADIOLI

UNDOUBTEDLY gladioli like plenty of moisture. Their habit and sword-like leaves suggest a water-loving subject, yet experience teaches us that badly drained, sour or water-logged soil is a great disadvantage. It is, of course, much too late to tender advice on the preparation of the soil for gladioli, but in dealing with culture at this time of the year one must refer to this phase, for their after-treatment depends to some extent on how the ground has been prepared.

When the plants appear through the soil frequent shallow hoeings will serve to kill the weeds and conserve moisture. Watering and feeding will be unnecessary until the early summer, when the main roots become established. In parts of America, where overhead irrigation has to be resorted to, gladiolus growers sometimes cover their beds with a half-inch layer of sand, a sort of dust mulch to retain the moisture. This procedure may be unnecessary in this country, but undoubtedly in most seasons a surface mulch of loose horse litter or spent hops would give us all the advantages of a sand mulch with none of its drawbacks.

Artificial fertilisers are best avoided by the inexperienced grower, and provided the soil has been deeply dug and richly prepared, there is little need for feeding in any shape or form. A dusting of bone meal hoed in round the plants in the late spring can, however, do no harm where it is surmised the condition of the soil is rather on the poor side. Bone meal is a "safe" fertiliser, it disintegrates slowly, has no harmful effect on the soil itself, and furnishes nutriment over a prolonged period "in instalments."

Watering and feeding from the time the plants are about 15ins. high will be found very beneficial if due regard is given to soil and weather conditions. The frequency and extent of same is entirely a matter for individual judgment, so much depends on the nature of the soil and the season. It is, perhaps, unnecessary for me to add that over-feeding and over-watering are alike detrimental and extra care must be exercised when dealing with badly drained soils.

ANTIRRHINUMS

IT'S only the fact that we grow and deliver especially good plants that we wish to advertise. The brightness, the long-flowering life, the wonderful adaptability of Antirrhinums (Snapdragons) are known to everyone. Although our plants are properly grown, transplanted, well rooted, hardened off, in all ways particularly good, as becomes a firm which reckon to do things well, the price is only

1/3 dozen. **8/6** 100.

Carriage paid on orders value 5/- and over, otherwise 9d. extra.

And these are the varieties and colours

Codsall Rose, delicate pink
Cottage Maid, pink, white throat

OLIVER & HUNTER'S
HARDY PLANTS
GROWN IN SCOTLAND

Much attention was attracted by our exhibit at Chelsea, where we had a unique collection of Alpine plants, including some of Captain Kingdon Ward's latest introductions from Tibet: Primula Florindæ and other new species, Meconopsis, Dracocephalum, Omphalodes, etc. Descriptive catalogue free on request

OLIVER & HUNTER
HARDY PLANT SPECIALISTS
MONIAIVE, DUMFRIESSHIRE

Please mention THE GARDEN *when writing.*

It is far better to give the plants a good soaking once every ten days or fortnight than to apply sparingly every three or four days. Of course, if a mulch has been spread around the gladioli, watering need not be so frequent. Do not allow the surface of the soil to become hard and "caked," but always stir the soil with the hoe the day after watering. Never apply icy cold water straight from the tap or a deep well; if a pond or ditch is not handy, let tap water stand for a day or two.

Liquid manure should be given in a very diluted form and the inexperienced would be wise to shun chemical fertilisers. That old-fashioned liquid manure made by suspending a bag of sheep manure and a little soot in a tub of water and allowing it to stand for a few days before use is quite good if well diluted.—C. H. A. S.

WORMS ON LAWNS.

GENERALLY speaking, the gardener should regard earthworms as most useful creatures. Worms continually renew the surface soil with finely divided earth brought from the subsoil and, by means of their burrows, allow the free penetration of rain and air to greater depths than would otherwise be the case. On lawns worms are unwanted because of the untidy appearance of their castings.

Several methods of dealing with a lawn badly infested with earthworms are to be recommended. In the evening, especially during mild damp weather, the worms will come out of their holes in large numbers in search of food, and can be collected with the help of a lantern. The watering of the lawn with some infusion will bring the worms to the surface in a more or less stupefied state. Where walnut leaves can be obtained, macerate these well in hot water, strain away the liquid and, when cold, sprinkle freely on the grass in the evening. Early in the following morning many worms can be collected. A similar effect is secured by using weak solutions of carbonate of ammonia, guano water, or clear lime water. In these cases, note that the solution should be really weak, or damage to the grass may result. Or one of the many proprietary preparations advertised in THE GARDEN, applied in accordance with maker's directions, may be used with safety and certainty.

When a lawn is thickly scattered with worm castings, choose a dry day and then use a stiff broom to pass over the heaps to break up and distribute the soil. Then use the mower, and there should be no clogging of the machinery.—S. L. B.

CATALOGUE RECEIVED.

Messrs. Clarence Elliott, Six Hills Nursery, Stevenage.—One of the best catalogues of alpine plants we have seen and one which all rock garden enthusiasts should have by their side, both for the interesting and admirable descriptions of the plants and the wide variety offered. The excellent line illustrations are the work of Mr. John Nash and are wonderfully lifelike.

THE GARDEN

VOL. XC.—No. 2845. JUNE 12, 1926

A TREE FAILURE

MANY of our trees are foreigners. New introductions pour in from abroad: some survive and in time are planted generally; they are successes and are good to look upon; others disappear in a few years, either because they are tender and so unsuitable, or because they are unappreciated. The common Monkey Puzzle, Araucaria imbricata, is a lamentable failure; and yet, why should this be? It is hardy—so hardy that I have seen two fine trees in a wind-swept garden on the coast near Stonehaven, where the furious wind had battered down every other tree within sight. The monkey puzzles were untouched, standing bolt upright in an easterly exposure, far more healthy than many in more sheltered positions, and clothed to the foot. It is a good grower; the biggest specimen that existed at Dropmore in 1871 was 51ft. high, 5ft. 10ins. round at 3ft. from the ground, and the spread of the branches was 28ft. At one time it was exceedingly popular, so much so that seedlings were sold at £10 10s. each, a gigantic sum, even more than the Wellingtonia fetched in the heyday of its boom. It is handsome, in a curious fashion, in leaf and certainly so in cone, which is blue-black and in size and shape like a coconut—it has the added attraction of bursting, when ripe, with a crack and falling in pieces, though it does not often cone in this country. And yet, with all these facts in its favour, it is a failure as a tree. It does not please or satisfy our tastes.

It was first found in Chile by Menzies in 1780, who succeeded in bringing back one or two plants alive. It created a stir then, and much more so when Lobb, travelling for Veitch imported a large quantity of seed in 1844. Then the craze began, and it became a universally popular tree. Many thousands must have been distributed between 1845 and 1890. Now, I suppose, it is the most despised tree that we have. I have never heard a good word said about it in this country. This sudden change from like—if it ever was admired—to dislike is odd. It must be a fine plant in Chile, as travellers have remarked on the grandeur of the forests and the grace of foliage in the mass, foliage that appears unsympathetic and gawky when seen on solitary specimens. Ordinary illustrations were poor in the middle of last century. Gardeners may not have realised that they were buying a plant that was difficult to place as an individual. They may have heard rumours of the existence of these enormous Araucaria forests and imagined that, as with the Wellingtonia, it made a fine ornamental tree. It may be that most of the buyers of seedlings followed each other like sheep and, having bought a pig in a poke for several guineas, were thrifty enough not to destroy it. It must be remembered that exotic conifers at that date were grown as specimen plants and not in plantations. Another reason for the unsuitable positions in which it was planted was undoubtedly the fact that its popularity so nearly coincided with that of the Wellingtonia, which undoubtedly was regarded by our grandfathers as a magnificent tree for specimen planting. They thought that a conifer of such an extraordinary appearance as the monkey puzzle would be equally suitable.

Whatever the reasons for this failure may be, one rarely sees a monkey puzzle that looks at home. Once, and once only, have I seen a group of five that was happily placed. Then they were planted in an irregular clump in a sloping field closely cropped by sheep and rabbits, with no other tree in the field, and backed by a rocky hill planted with beech and spruce and plane. I must say that they looked extraordinarily well in the autumn, blue-black against a hillside that shone with the russets and yellows of dying foliage. I have never heard of any plantation of any size in this country: perhaps it exists. If so, it is probably a wonderful sight. One of its great faults as a solitary tree is the existence of dead and scrubby lower branches. This probably does not occur when it is planted in mass formation. In any case, here is an odd instance of a stranger that has lost its personality in its wanderings so far from home. We have no place to give it, either in our woods or in our gardens. It gives us little or no pleasure to see it, and it must lead a lonely existence on its own. Perhaps there is something that is lacking in us, as we are so unsympathetic towards it: perhaps the younger generation dislike it as they recall that it was part and parcel of an extremely artificial period of gardening—a period which has now been swept aside. It is true that a few plants have sufficient character and beauty to have conquered this feeling of distaste, but the Araucaria is not among them. The feeling that it gives is one of a stately but sulky indifference. Theoretically, it is a wonderful sight, that should cause a thrill: actually, it is a dismal failure.

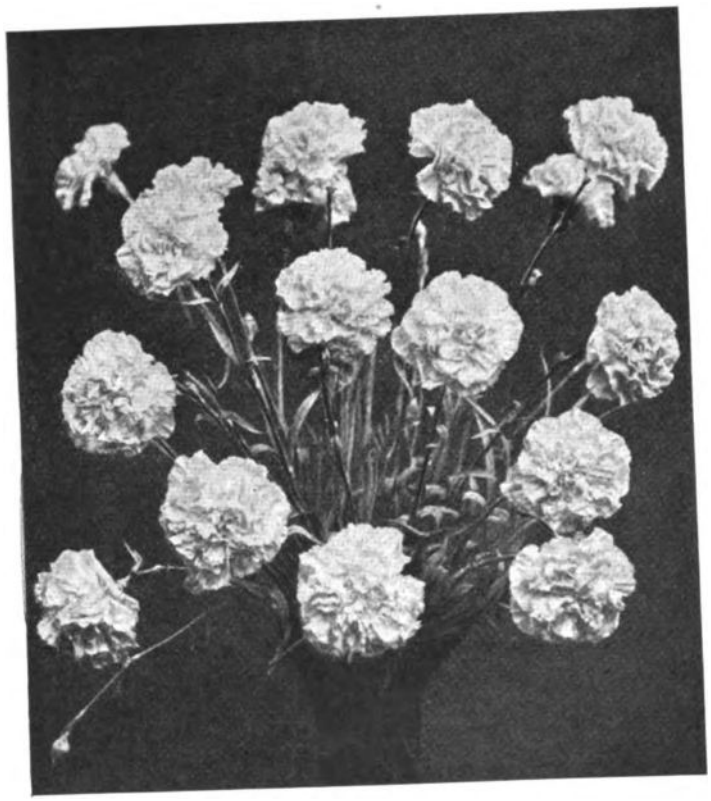
WORTHY PLANTS.—III.



CARNATION LADDIE.

SO popular is the perpetual-flowering carnation that it is probably supreme at the present time as a cut flower. Undoubtedly it has improved out of all recognition in the past few years. Varieties come and varieties disappear from cultivation as improvements are made; yet it is difficult to pick and choose what is the best when so many that are first-class are now on the market. One that certainly stands out is Laddie, for here is an ideal general-purpose carnation. The large flower is of good shape; it is a free bloomer and of excellent constitution; while the colour, a pale salmon pink, is so pure and so refined that it will go with anything. It is certainly one of the most popular of all market varieties, and it is to be seen in every florist's window. Yet, oddly enough, it is not so popular among amateur growers as it should be. Perhaps this is because familiarity breeds contempt, a fallacy when dealing with flowers. We strongly advise all carnation lovers who do not yet grow Laddie to buy a stock at once.

AT a recent meeting of the Gladiolus Committee, held at Chelsea, it was decided to form a Gladiolus Society as soon as possible. Arrangements are already being set on foot with this end in view. The membership fee is 5s. per annum and we understand that the Committee intend issuing an annual year book, the first one of which will be published shortly. This action on the part of a few enthusiasts deserves every encouragement and we hope that all lovers of the gladiolus will see their way to become members and assist this newcomer to the list of horticultural societies to become as flourishing and as important as its more mature neighbours devoted to the carnation, the iris, the rose, the daffodil and the sweet pea. There is certainly a great future for the gladiolus as a garden plant and once the Society gets under way it will undoubtedly prove of the greatest help to all amateurs who are taking up the growing of the flower. We wish it all success.

IT would appear that many amateur gardeners are under the impression that the Royal Horticultural Society's Amateur Show, which is to be held at Vincent Square on the 22nd next is only open to Fellows of the Society. We have been asked to state that this is not so: that all amateurs are cordially invited to exhibit, and that there are no entrance fees. Schedules may be obtained from the Secretary, R.H.S., Vincent Square, Westminster. It is to be hoped that all amateurs who can, will endeavour to stage an exhibit and so make the Show the success it ought to be.

A PAMPHLET has just come to hand consisting of a list of the publications of the Arnold Arboretum of Harvard University and writings of its staff since its inception in 1873. It is a remarkable monument to the activities of the energetic and capable staff of one of the greatest of the world's arboretums, evolved principally owing to the genius of its founder, Charles Sprague Sargent, ably assisted by E. H. Wilson, Alfred Rehder and others. No one will question the work that has been accomplished by this small band in adding to our knowledge of the ligneous flora, principally of the Temperate zones and particularly of North America and the Far East; but how large and important their labours have been cannot be realised without a glance through the comprehensive list of books, papers and publications that have been published by the Arboretum or written by its staff.

FOR the benefit of new readers we give the rules and list of prizes for THE GARDEN Sweet Pea Competition, which opened in our last issue.

RULES.

1.—A list of your choice of the six most popular sweet peas to be sent in in order of preference on the coupon to be found on page iv of this week's issue of THE GARDEN. *No alternative* varieties will be allowed in the one list, but readers may send in any number of lists, provided that they are written on the special coupon to be found in this and the following four issues of THE GARDEN.

2.—Coupons must reach this office not later than Saturday, July 17th (after which date no coupons will be accepted).

3.—The popular vote will be final, and no correspondence will be entered into over this competition.

4.—Envelopes must be marked *Competition* and addressed to THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C.2.

5.—The Editor will not be held responsible for letters missing in the post.

6.—The result will be announced in THE GARDEN in the issue of August 28th.

7.—The prizes are awarded to those whose lists correspond most closely to that arrived at by the popular vote.

8.—If two readers tie for the first place, the first and second prizes will be equally divided; if two for the second place, the second and third prizes will be equally divided.

9.—The Editor's decision on all points will be final.

PRIZES.

1ST PRIZE.—Goods worth **£30** from any advertiser in the pages of THE GARDEN.

2ND PRIZE.—Goods worth **£10** from any advertiser in the pages of THE GARDEN.

3RD PRIZE.—Goods worth **£5** from any advertiser in the pages of THE GARDEN.

20 CONSOLATION PRIZES of **5s.** each from any advertiser in the pages of THE GARDEN.

AMONG THE ARTICLES IN OUR NEXT ISSUE WILL BE:

A LITTLE PINK AND GREY GARDEN, by Edward Cahen.

THE VALUE OF FOLIAGE—I, by John Hill.

SOME PRIMULAS OF THE WESTERN ALPS, by Henry Correvon.

Digitized by Google

NATIVE PLANTS of OUR GARDENS—II

BY DR. R. LLOYD PRAEGER.

IT is when we come to plants suitable for the rock garden that the native flora comes especially to our assistance, for many of the very best rock plants grow wild in Britain, as well as a large number of others that are welcome. Let us take first a few of the most valuable. The beautiful pasque flower, Anemone Pulsatilla, native on chalk downs and limestone pastures, is a lovely object in early spring. Give it a sunny spot and a deep, dry root run and it grows freely. Of the familiar and favourite wood anemone (A. nemorosa) there are blue, reddish and double varieties which are of exquisite beauty. The cushion pink, Silene acaulis, found on many of our mountains, makes fine dense mats of fresh green starred with dainty pink flowers; but it never blossoms with us so profusely as it does in high northern regions. Dryas octopetala, the mountain avens, another plant of northern climes and high mountains, widely though locally spread in our islands, is quite one of the loveliest and most characteristic of rock plants, whether in flower or fruit, and under the ordinary rock garden conditions of thorough drainage it grows freely. Not so showy, but full of charm, is the alpine lady's mantle, Alchemilla alpina, with its dainty silky leaves and small green flowers. As its name implies, it also is a plant of our mountains.

Several of our native saxifrages rank among the best of rock plants, for instance, S. oppositifolia, though so far as I am aware most of the large-flowered forms which are so especially gorgeous in early spring come from the Alps and other Continental mountains. Of that excellent plant the London pride (S. umbrosa) the large coarse form which fills so many waste corners in gardens is the Pyrenean variety of the plant. Many of the native forms, from the west of Ireland, have none of this coarseness of growth, and make in the rock garden elegant small tufts, with a considerable variety of leaf form, due in some cases to crossing with that other Irish saxifrage, S. Geum. S. aizoides is a not infrequent inhabitant of our mountains; but the striking blood red variety, the best for the rock garden, so frequent in Norway and the Alps, does not, so far as I am aware, deck any of our own mountain streams. The rose-root, Sedum roseum, which is rather common on British mountains, is an excellent rock garden subject, of neat growth and striking form. A very different plant, as slender and fairy-like as the last is massive, is the twin-flower, Linnæa borealis, which grows in Scotch pine woods. Give it half-shade and peat, and it runs freely about, with graceful opposite-leaved shoots and delicate drooping flowers borne in pairs on short, erect stalks. More dainty still is the ivy-leaved bellflower, Wahlenbergia hederacea, native in the western parts of the British Isles, a real fairy plant, indescribably dainty and delicate, with little campanula leaves and pale blue, open campanula flowers on thread-like stems. It needs moisture and shade. Another dainty thing of northern woods is the chickweed wintergreen, Trientalis europæa, which looks delightful running about under taller things in dry peat—a slender little thing with numerous stems bearing each a whorl of leaves and a single starry white blossom. Then one of the best of all, the gentians—that lovely and often heart-breaking genus of mountain plants—is a native of the north of England and the west of Ireland. This is G. verna, the spring gentian, a good clump of which is one of the rock gardener's proudest posessions. Another north of England rarity, found in thickets on limestone, is the lovely lady's slipper, Cypripedium Calceolus, the most striking of British orchids. It is not difficult in a choice pocket of the rock garden in light, well drained, limy soil. One might ramble on in this way for another page, but it is necessary to pass to other groups. To show that the list of British plants which contribute to our rock gardens is not nearly exhausted we may simply present a number of others in list form:

Thalictrum alpinum
Meconopsis cambrica
Helianthemum canum
vulgare
Dianthus deltoides
cæsius
Lychnis alpina
Arenaria ciliata
Sedum rupestre
Cornus suecica
Antennaria dioica
Phyteuma orbiculare
Campanula rotundifolia
Vaccinium Vitis-Idæa
Arctostaphylos Uva-ursi
alpina
Armeria maritima
Geranium sanguineum
Genista tinctoria
Astragalus alpinus
Hippocrepis comosa
Saxifraga granulata,
hypnoides and allies
Sedum Telephium
album
Vinca minor
Thymus Serpyllum and allies

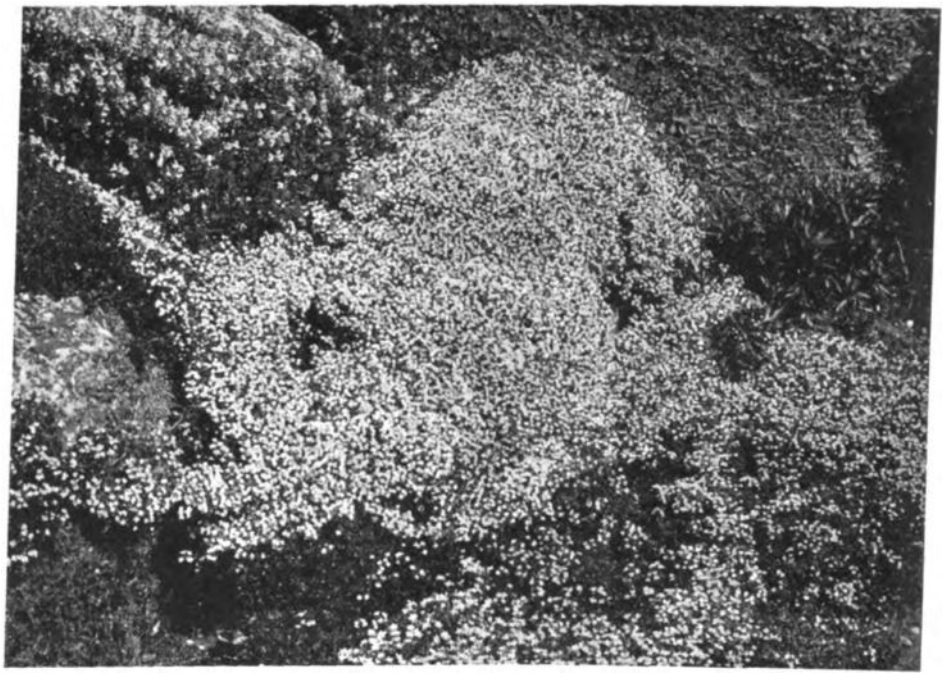
Salix reticulata,
herbacea,
Arbuscula
Sisyrinchium angustifolium
Maianthemum bifolium.

Allied for garden purposes to the rock plants are several other groups. Almost all our Ericaceæ need dryish peat, and they are almost the only British plants which do—peat bed conditions, not bog garden conditions. Almost all are worth growing, some for their beauty in the wild form, while others yield colour or other varieties preferable in the garden. Such are the ling, Calluna vulgaris, and the group of the heaths—Ericas cinerea, Tetralix, vagans, ciliaris, mediterranea and Mackaii; Andromeda polifolia; the lovely Irish Daboëcia polifolia; the rare Scottish Bryanthus cœruleus and Azalea procumbens, the last being matched in difficulty of cultivation by the graceful pyrolas.



THYMUS SERPYLLUM, AN ATTRACTIVE NATIVE FOR THE ROCK GARDEN.

The bog garden does not receive many denizens from among our native plants, but two delightful primulas, P. farinosa and the better P. scotica, are best so treated. We have also the beautiful grass of Parnassus, the tiny cranberry and some interesting orchids, such as O. maculata and O. latifolia and their allies, and the marsh helleborine, Epipactis palustris. Those who love, and will take trouble over, tiny plants will rejoice in our native insect-eating species belonging to drosera (sundew) and pinguicula (butterwort), particularly the splendid P. grandiflora. For these plants I recommend

CYPRIPEDIUM CALCEOLUS, THE FINEST OF OUR NATIVE ORCHIDS.

THE LATE-FLOWERING ORANGE SCARLET KNIPHOFIA CAULESCENS.

a pan of mixed peat and sphagnum on a sunny windowsill, the pan being kept always wet by being set in a dish with an inch of water.

On the other hand, Great Britain, being a country with a sufficiency of rain in all its parts, its flora does not yield many plants which in the garden need exceptionally dry treatment. Of the few which are worthy of cultivation the sea cudweed, Diotis candidissima, with its remarkably woolly stems, leaves and flower-heads, and the sea holly, Eryngium maritimum, are the only ones which are in any way particular. Both need all the sun and exposure we can give them, and a deep gravelly root run to correspond with the open beaches on which they naturally grow. Diotis is one of our rarest British plants. Other plants of gravelly habitats which are worthy of a place, such as the horned poppy (Glaucium luteum), sea wormwood (Artemisia maritima) and oyster plant (Mertensia maritima) are not particular, though they need a dry, sunny place to show their beauty.

For the water garden our own country yields the white and yellow water lilies, and that curious plant Limnanthemum peltatum, which looks so like a little water lily, but is really close to the gentians. Then the water violet, Hottonia palustris, with its whorls of pale lilac flowers, is pleasing for a pond, and we may add the curious water soldier, Stratiotes aloides, like a submerged aloe with three-petalled white blossoms. For the edge of the pond the best natives are the flowering rush, Butomus umbellatus, and the arrow-head, Sagittaria sagittifolia, with its striking leaves.

British bulbs are not many in number, but they include a daffodil, a snowdrop, two snowflakes, a gladiolus, a tulip, a grape hyacinth and a few others—not to mention a number of garlics. The most striking of British bulbous plants is the snake's head, Fritillaria Meleagris, deservedly common in gardens, for it is easy and highly ornamental, with its strange, hanging, chessboard flowers.

Lastly, a word must be said for our native ferns. Many of them are as elegant as any of their race—the noble royal fern, the graceful oak fern, buck fern and mountain bladder fern, the stiff prickly holly fern, and the tufted parsley fern, which many people find not too easy to grow. For limy chinks in the rock garden we have quite a lot of pretty spleenworts and the brown-backed scale fern. The sea spleenwort does best in a cool house, where it is joined by the lovely maidenhair; and, lastly, we have the delicate Killarney fern and the two tiny filmy ferns, which need all the moisture and shade we can give them.

RED HOT POKERS FOR THE AUTUMN GARDEN

AMONG the outstanding flowers in the autumn garden are the kniphofias, known also as tritomas and torch lilies, and to thousands of folk as red-hot pokers. Some of these distinct and brilliant flowering perennials come to us, it is true, even while summer lingers, but the majority of this large and interesting family are later visitors, and give of their best in the early autumn.

It would be misleading to say of kniphofias, without any qualification, that they are very easy to cultivate and present no difficulties to the grower, when one remembers that last winter, particularly on cold, heavy soils, there were many losses, not because of frost entirely, but also on account of snow and continued rain finding ingress to the crowns and causing them to decay. By making due provision one can, however, guard against failures in the winter to a great extent by affording temporary shelter to the plants from the worst weather. One method is to tie the long leaves up to a central stake in the autumn and place a mulch of cinders round the roots, or partly envelop the plants in straw or bracken. Those who tidy their garden late in the year to the point of neatness by cutting down some of the plants that have ceased to flower, should, at any rate in the case of kniphofias, make an exception, and defer removing withered foliage until towards spring, as it acts as a foil against frost. Kniphofias resemble other plants in the garden—peonies and gypsophilas for example—in that when once they have become established

Digitized by Google

and are doing well they ought not to be disturbed. Bearing this in mind, it is obvious that a suitable position should be found for them in the first instance, as they will go for years without the necessity for removal arising. A sunny quarter is best for them, and ordinary garden soil will answer, provided one is prepared to give them a mulch of rotted manure every season, about June —cow manure for preference. Planting may take place in March or April, at which time they may be divided; but division of kniphofias should not be undertaken unless the clumps have become very large—indeed, they will go for five or six years, and sometimes longer, without signs of deterioration. One important point in the planting of kniphofias ought not to be forgotten: it is the question of drainage. This should be ample, and is best secured by placing small pieces of brick, 2ft. or so below the surface, as one would do in planting alstrœmerias. This, the orthodox method of growing these flowering plants with their wonderful spikes of colour may, perhaps, be dispensed with where the soil is sandy and well drained.

A BLAZE OF GLOWING RED-HOT POKERS BESIDE THE POOL.

Kniphofias are so varied that one can select sorts ranging from comparative dwarfs—not more than 2ft. in height—to the giants of nearly 7ft. Some of them, too, are possessed of colours so intense that distance, if not lending enchantment, at least softens their tones so as to make them even more attractive. Particularly is this to be noted when they are planted near to conifers or on the margins of shrubberies with intervening space of lawns that only serve to heighten their beauty in the time of flowering. One needs but few kniphofias in a garden of modest dimensions, as they improve as the years go on, and every season adds to the number of the spikes. Often in mild autumns one may have their torches of flame into October, and it may be said of them also that they lighten up the most sombre corner. While kniphofias are best known and possibly more highly appreciated because of their height—as to merit the designation "imposing"—it is worth remembering that the dwarf sorts have their own peculiar charm and make capital tenants for certain positions in the rock garden. Incidentally, it may be mentioned that, although for many years we have prized the taller sorts for borders, we do not forget that they constitute a very great attraction, when opportunity offers, for planting in proximity to a pool or ornamental water, but not near enough for them to feel ill effects of stagnation at the roots caused by excessive moisture.

In some parts of the country kniphofias are favourites in cottage gardens, and grow to a large size, confirming the opinion that they will go for quite a long time before needing removal. Cottage gardeners are often conservative in regard to the plants and shrubs about their homes and doors. They do not care to meddle with them, looking upon them like old friends, as being part and parcel of the place. One frequently finds this exemplified in huge clumps of lupins, trolliuses, hemerocallises, also in bushes of lavender and kerria; in "lad's love" in borders beside the door, and, not least, in the sweet briar near the garden gate. The plants mentioned are typical of those to be found in widely different districts of rural England, from the Cumberland fells to the Cotswolds, in the hamlets of the Derbyshire dales and the villages skirting the seaboard of Mendip. About many of these cottage homes I have, time and again, noticed the gardens where kniphofias are grown. Perhaps it has been on some late autumn day when the setting sun has cast a spell over the garden, and the tall spikes, towering above other things, have appeared lit up with flames as of fire—veritable studies in scarlet and vermilion, yellow and coral, orange and crimson, almost compelling one to stay and admire them. In this large family there are many sorts, beautiful and striking, but we confess to a fondness for the older and best known forms, of which a brief list is given. All are good garden plants and worthy of a corner in one's own garden.

THE MASSIVE SPIRES OF KNIPHOFIA CORALLINA.

K. Uvaria.—4ft.; August-October; coral red and yellow.

K. caulescens. — 4ft; September-October; orange scarlet.

K. Burchelli.—4ft.; July-September; scarlet, tipped green, flower stems spotted black. Very showy.

K. nobilis.—6–8ft.; July-August; rich scarlet.

K. pumila.—2ft.; June-July; orange scarlet.

K. Macowani. — 18ins.; July-August; deep orange scarlet.

K. Goldelse. — 18ins.; June-July; yellow.

K. corallina.—2ft.; July-August; coral scarlet.

K. Lemon Queen.—4–5ft.; August-October; lemon yellow.

W. LINDERS LEA.

NOTES OF THE WEEK

PILLAR PLANTS IN THE CONSERVATORY.

PILLAR plants, to be effective, need not be those of true climbing habit, though the latter include some of our most beautiful subjects and should be used judiciously. I say judiciously, because it is very important that the structures are not overcrowded. There are other kinds of plants in the conservatory and these, too, must be considered. Such plants as myrtles may be trained to pillars and prove to be very charming in that position; but, though they are evergreen, the necessary constant clipping prevents any flowering. It is also important that the size of the structure be duly considered, especially the height. To introduce naturally large-growing kinds of plants into a small house is wrong. For example, the acacias would look really charming clothing pillars in a large structure, but quite out of place in a small one, if it is the intention of the owner that the plant shall develop. Acacias are not true climbing plants, but they are splendid pillar subjects in lofty houses. Acacia Riceana, A. longifolia and A. pubescens are very suitable.

Bignonias, too, are only suitable for the largest structures, and they present a very fine appearance in such. In the warm conservatory of medium to large size Bougainvillea glabra and B. speciosa are very effective. The most exposed and sunniest pillars are the best on which to train the plants. Cobæa scandens and its variegated form will soon fill a large house, but as the plants bear severe pruning they are suitable for clothing tall pillars. Habrothamnus elegans is, also, a big-house plant. Its large green leaves form massive pillars from floor to roof-glass. The passifloras are all suitable; but Tacsonia Van Volxemi is of outstanding beauty when trained to a pillar and also allowed to spread to the wires under the roof-glass. Heliotropes and Jasminum grandiflorum, also J. azoricum, are all attractive pillar subjects; it is so easy to enjoy the scent to the full when passing by.

For smaller houses—and they may find a place in large ones—the following kinds are charming: Hoya carnosa; Lapageria alba and L. rosea; ivy-leaved pelargoniums; Plumbago capensis; Rhynchospermum jasminoides, evergreen, fragrant flowers; Solanum jasminoides; sollyas, these are fine twining plants; tecomas; thunbergias; tuberous-rooted tropæolums; and the canary creeper, the last named for a small, cold structure.

Practically all the pillar plants are now growing freely, and it is an easy matter so to train each specimen that it will occupy the position allotted without being too stiffly trained. Tying in and cutting out old useless branches is work that needs weekly attention. Then there is the cleaning of the foliage, the watering, top-dressing and feeding. As growth is now free, some nourishment will be needed, and its immediate effect can be noted with a view to future guidance.

Cleanliness is absolutely essential to the good health and appearance of the plants. Such subjects as lapagerias, possessing smooth leaves, may be sponged. Leaves with a rough surface must not be sponged. All stems should be kept clear of scale and, if aphides appear, fumigate to get rid of them.—HANTS.

THE GROUPING OF PLANTS FOR MUTUAL WELFARE.

IF it is true that to every plant its neatest neighbour is an actual or potential enemy, it is equally true that rivalry for place and power may be, and often is, distinctly beneficial to the individuals concerned, as witness the glorious healthiness of an alpine meadow. The struggle for existence certainly perpetuates the fittest, but the comparatively weak may prove a friendly aid to the strong, and the latter can often be a tender nurse to the feeble, the prevailing note being one of perfect amity.

ARMERIAS AND WILD WOODRUFF IN CONJUNCTION.

AUBRIETIAS, ARMERIAS AND ARENARIA MONTANA GO WELL TOGETHER.

The running together of rock plants may be unorthodox. Gardeners who are disciplinarians may strictly forbid such transgressions. But, within limits, I am "all out" for this close association, because experience convinces me that so many plants are healthier when rubbing shoulders with neighbours, and healthy plants are happy and naturally beautiful.

Why certain, if not most, plants delight in this mutual intercourse is not always clear. We know that a well covered ground is kept cool and uniformly damp, thus preserving surface roots from injury. We know that a large number of subjects which would otherwise be tossed about or frost-bitten derive anchorage and shelter from congenial companions, that others are sun-screened by taller ones, and then there is, doubtless, much in root association. In this last I often think there is a deal that is still to be discovered—quite apart from partial parasitism, which may be anything but harmful—and there is surely something, some temperamental element in plant life, to account for the misery which some subjects endure from isolation and their remarkable recovery when comforted by the sympathetic touch of agreeable company.

Gentiana verna is often a disappointment, and a companion plant is generally recommended as a panacea for its troubles. But this is only one of many alpines found growing in turf or in masses which are undoubtedly better for close association. Dryas octopetala, Linnæa borealis, the dwarf heaths and their nearer kindred, Arenaria montana, many lithospermums, silenes and alpine phloxes, all enjoy being one of a crowd, and it is not difficult to select plants whose colours and habits of growth will blend amicably one with another.

To be more definite, our finest masses of Daphne Cneorum have growing among them Linum narbonense. The latter is very robust, its partner undoubtedly enjoys the light sun-screen which rises above it when its flowers are past, and we get the lovely masses of blue right into late summer. L. perenne is equally valuable in the same way among the many alpines which dislike too hot a sun and selected forms of the common harebell—often self-sown—we use for a like purpose. That dainty plant, Sedum pruinatum, is never so happy as when threading its way among prostrate thymes. Arenaria montana grandiflora swarms over the white-flowered, golden-leaved lesser periwinkle, but this cheerful early bloomer has the field to itself before the sandwort is in full spring growth. Some old roots of Gentiana acaulis which always flower well have prostrate thymes and Campanula pusilla for company, the latter delighting to weave its way in a root-run kept firm and cool by the former, and it breaks into flower when the gentian is over.

Any number of such examples might be given, but I must confine myself to one more. The ivy which covers many of the banks and slopes of this garden is not only instrumental in holding in place a gravelly, trickling, dry soil, but its thatch of green renders the latter cool enough to grow many things which would otherwise be a failure. This ivy—believed by not a few to be poisonous to plant life, a parasite and what not!—serves as a cooling mulch, as well as a trap for fallen leaves, which it converts into humus, and in it we have happy, colonies of snowdrops, daffodils, scillas, anthericums, some of the easier lilies, aquilegias, lysimachias, lily of the valley and lots of other subjects, not to mention shrubs, which undoubtedly owe much of their well being to the co-operation of their carpeting friend, which, if sometimes a little too willing, is actually one of our most efficient, and certainly most ornamental, labour-savers. —A. T. JOHNSON.

BERBERIS NEUBERTII

THERE are many species and hybrids to the genus berberis which have deservedly achieved popularity for their value as decorative garden plants. Berberis Neubertii is not one of this number, but stands almost alone as a plant devoid of the beauty of flower and fruit which others possess. It is, however, a plant of no little scientific interest. It was raised some seventy-five years ago in an Alsatian nursery as the result of a cross between Berberis (Mahonia) Aquifolium and B. vulgaris. In habit it resembles the former. A close examination of the foliage reveals great variability, and on one twig may be found leaves of several distinct forms. Those at the base of a young shoot are usually large and composed of three or more leaflets with finely toothed margins. Higher up the shoot the leaves tend to become smaller, thicker and more coarsely toothed, those at the top resembling holly leaves. When these fall, there spring from their axils tufts of thin, finely toothed simple leaves not unlike those of the common barberry.

The similarity of some of the leaves to those of the holly has caused this plant to be known as B. ilicifolia, but the species of that name is a much finer and, unfortunately, much rarer, evergreen shrub bearing very beautiful orange-yellow flowers.—N. K. G.

THE VARIED FOLIAGE OF BERBERIS NEUBERTII.

A FINE MESEMBRYANTHEMUM.

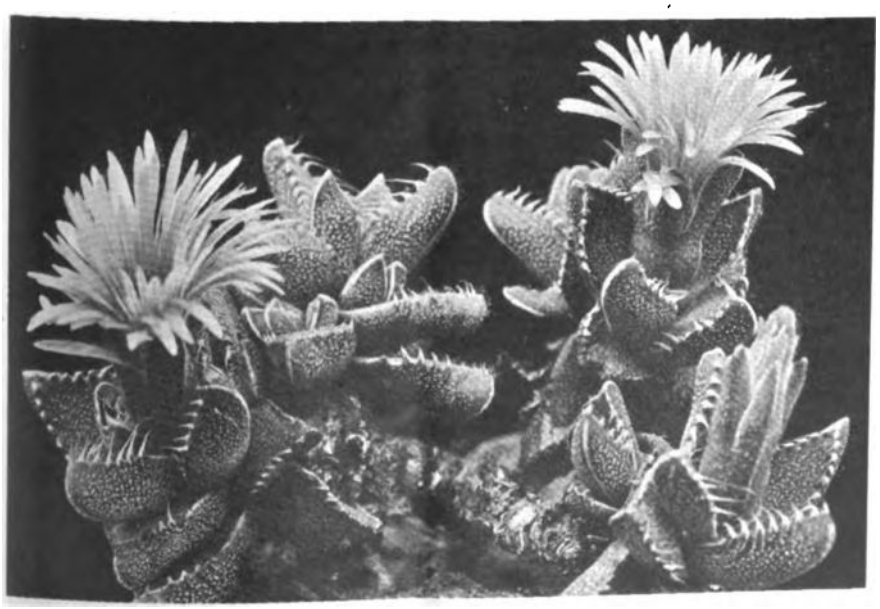
A VERY handsome mesembryanthemum which is of the easiest culture is M. tigrinum. This species, which is very nearly hardy at any rate in the south of England, is best grown in a pot or in a sheltered situation in a rock garden. In the latter position it might be an advantage to give a little protection with dry fern during cold weather. M. tigrinum flowers freely during the summer if it can be fully exposed to sunshine. The flowers are large and of a very pretty lemon colour. Even when the plant is not in flower it is very attractive on account of the silver-green colour of its leaves. These are adorned with what appear to be formidable spines, but, as a matter of fact, the processes are quite soft and incapable of hurting anyone. This, like most of the mesembryanthemums, can be propagated easily by inserting pieces pulled off with a heel and laid on damp sand in the sun under a glass. The soil for this mesembryanthemum should be a mixture of loam, sand and leaf-mould, to which it is an advantage to add a little lime rubbish.—S. L. B.

ARUM LILIES IN THE OPEN.

How to Establish Them in the Water Garden.

IT is rather surprising that more people do not grow the beautiful Calla lily (Richardia æthiopica) out of doors. Anywhere in the south of England, and even elsewhere, if the position is not too exposed, the Calla lily may be regarded as a hardy aquatic. Quite good results are also secured by growing this plant in a cool moist border which is well sheltered from the north and east. Well grown outdoor clumps of the Calla lily are so handsome that it is worth while making special efforts to secure the happiness of the plant. Without doubt the best results are secured by treating the Calla lily as an aquatic. A suitable position is found in a pool where there is a depth of from 18ins. to 2ft. of water. Here the roots will be quite secure from any frost which we are at all likely to experience in this country. Planting is carried out during the summer in this way. Fill some old and rather large baskets with soil and, in this, insert the roots. Pack the soil in tightly and, on the surface, add some heavy stones to keep the earth from washing away. Then plunge into the water, and in course of time the baskets rot and the Calla lilies become completely established.

The vigour of growth when Calla lilies are treated in this way is surprising. The writer is familiar with some plants that have been growing in an outdoor pool for many years, and these have grown and increased amazingly. In themselves the handsome leaves produce a very fine effect, while, when the plants are in flower, the appearance is still further enhanced. Calla lilies increase quite freely from self-sown seedlings, and, in addition, they extend laterally from the old roots on all sides. During a sharp frost the plants will be cut right down to the water's edge, but this does not harm them in the least. Directly the mild weather returns the shoots come up again as strongly as ever. In fact, it has been noted that when the plants die right down below the surface they usually produce a far finer display of flowers than if they have remained in a more or less active state of growth for most of the winter season. In very mild localities the Calla lilies will flower out of doors about April or May. In other situations the blossoms come along in June. As has been indicated, it is well to allow a certain number of the flowers to set seed and to permit these to fall into the water. This will ensure a supply of vigorous young seedlings, which, in course of time, will develop into flowering plants.—S. LEONARD BASTIN.



THE LARGE LEMON COLOURED FLOWERS OF M. TIGRINUM MADE THE MORE EFFECTIVE WITH ITS SILVERY GREEN LEAVES.

SPIRÆA FILIPENDULA.

A Fine Border Plant for Cutting.

IMPROVED varieties of our common wild flowers are not unworthy of a place in the garden, and of these we mention two spiræas, the double filipendula and double ulmaria. The former sends up a slender stem from a lowly rosette of leaves, the flowers being very full and delightful. The latter, which prefers a wet corner, is almost 3ft. in height, and a large dense bunch of white flowers 6ins. in diameter is produced on each stem. While both look quite well in the border, we always find them in favour for cut blossom; the flowers seem to prove attractive to everyone, and they look well in a vase. S. ulmaria, the queen of the meadow, is just a trifle too heavily perfumed for most, but otherwise it is all right. Both can be grown in a mixed herbaceous border and require no special care or attention.—LANARKSHIRE.

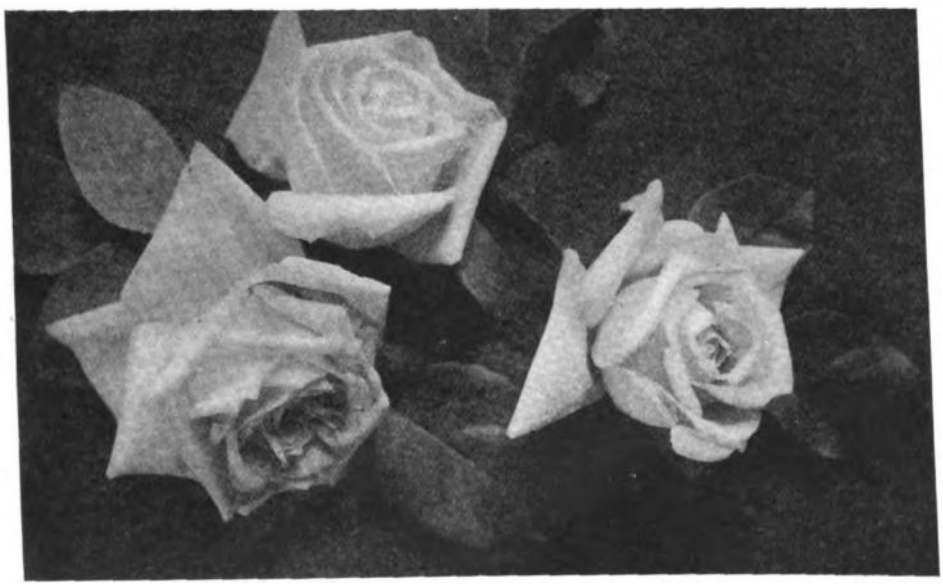
ROSES IN RETROSPECT

THE riotous beauty of the rose displays shown at Chelsea this year must recall to many of us memories of roses of by-gone days that have now passed into oblivion, and while the memory of Chelsea still lingers fresh in our mind, it is pleasant and helpful to put into perspective and review those familiar roses of the past which secured their measure of popularity. Of those who grew and loved them, the stalwart rosarians of Victorian days, with rare exceptions, have passed into the Great Unknown. Fortunately, some are still with us, and of those, few can speak with more knowledge of "our grandmothers' roses" than our good friend Mr. J. H. Pemberton.

Most of us, therefore, can only compare the roses of to-day with those of the last forty years by references to the rose literature current at that time, as adjuncts to our own fleeting memories, and for this purpose the Rosarians' Year Book serves as a useful reminder.

Harking back in decade periods, we find in the little annual of 1886 the most popular roses then were the fleshy white Captain Christy (one of the oldest hybrid teas), the bright red Marie Baumann, or the dark red Louis van Houtte.



STILL ONE OF OUR FINEST ROSES, MARECHAL NIEL.

All these have now almost passed out of existence, chiefly by reason of their weak growth and frail constitution.

It is of interest to note that in 1886 a new rose, Mrs. John Laing, was being written about, though it had not then leapt into the popularity accorded later.

Single roses, too, were not of the decorative and perpetual-flowering varieties as we know them to-day, but belonged more properly to what we class as species roses.

The next period of ten years culminated in 1896. That year might be described as Her Majesty year, and the heavy blooms of varieties such as this were not only fashionable throughout that period, but were regarded as nearly perfection. This, in spite of the fact that this variety, as an example, had many more faults than we in these more enlightened days should consider a popular rose ought to have. It was a shy bloomer, with never a bloom in the autumn, notoriously subject to mildew, and fragrance was almost unknown.

In these days Lord Penzance was hybridising a new race of single roses—Penzance briars—beautiful when in their bright summer blooms, but with one crop of flowers only; although their pretty autumn effect when crowded with bright red hips gave them a decorative quality which should be mentioned to their credit.

Of climbers the most popular then were William Allen Richardson and Crimson Rambler—the latter only recently arrived, while Grüss an Teplitz was the favourite garden variety. Tea roses were also still going strong, though their doom as regards popularity was imminent.

The year 1916 found Frau Karl Druschki and Dean Hole pre-eminent as exhibition roses, the former ever popular to-day as the best pure white all round rose, but, alas! scentless; and the latter practically useless as a garden variety, and consequently now almost discarded.

Blush Rambler and Hiawatha had come to fame as climbers. Both of these have made a good claim for their continued use in future. Garden roses by now had come to the front—supplanting both the heavy exhibition type and the colour-lacking teas, and we find Mme. Edouard Herriot and Lady Hillingdon all in vogue, and both are still with us and likely to remain, even though they have been improved upon.

We come then to 1926, to find the exhibition roses relegated to second place in the N.R.S. Schedule, presumably by the dictates of popularity, but whether the same high standard of rose cultivation will be maintained in future is, perhaps, questionable, and time alone will vindicate this.

The "garden rose" may then be considered to-day to be reigning supreme, and of such the present number of good varieties is almost countless, for so many are really good garden roses.

Mr. William Paul's fine book, "The Rose Garden," contains as a frontispiece a beautiful coloured illustration of Maréchal Niel—still one of our finest roses if one can only succeed in growing it, but the so-called ideal rose of those good old days required to be either globular, cupped, compact, or expanded, so far as shape for judging was concerned, whereas the successful exhibitor to-day seeks for a good point—shape—and would consider a rose as over if it showed its centre.

In view of our more recent acquisitions, it is perhaps questionable whether the late Dean Hole would reiterate to-day the memorable words in his book about roses: "If I were miserably sentenced for the rest of my life to possess but a single rose tree, I should desire to be supplied on leaving the dock with a strong plant of Gloire de Dijon." Would he not to-day have substituted General McArthur or Betty Uprichard?

The law of the survival of the fittest may farther be illustrated by a few selections from the gold medal awards of the N.R.S.—1883, Her Majesty, a heavy exhibition rose now rarely grown or shown. 1885, Mrs. John Laing, popular as a town rose. Not profuse, but still an old favourite which few of us have the heart to discard. 1889, Souvenir de S. A. Prince, a tea rose with a meteoric and brilliant career, only really popular with the little band of enthusiastic tea rose exhibitors. 1892, Mrs. W. J. Grant, beautiful, but too thin, whereby it did not secure confidence. 1893, Turner's Crimson Rambler, striking a new line of popularity, which however has since been quite eclipsed by something better. 1904, Mrs. O. G. Orpen, the precursor of the single decorative roses, followed by, in 1905, Irish Elegance, which up to quite recently was always the most favoured rose chosen for the ladies' dinner table classes. It still finds a place in most gardens as the big 6ft. high bushes provide an unfailing source of supply to the housewife for house decoration blooms.

The following years marked the gradual fall of the exhibition bloom, and the corresponding rise of the free blooming garden variety, culminating in 1921 with Betty Uprichard, at present considered the most popular garden variety.

By way of an interesting comparison, let us consider three typical roses, ancient and modern, which are still grown, namely, Mrs. John Laing, produced by Bennett in 1887, Mme. Abel Chatenay, produced by Pernet-Ducher in 1895, and Betty Uprichard produced by Alex. Dickson and Sons in 1922.

The blooms of Mrs. Laing nearly always come good in shape, in fact it was a by-word among exhibitors that the blooms were fewer but better than those of most varieties.

Digitized by Google

The blooms are of semi-globular shape, and of bright colour. Plants have few imperfections, are not very liable to disease, and the light foliage is unique, harmonising with the pink blooms. Scent is excellent.

In Mme. Abel Chatenay we have to contend with a consistently difficult grower. Owing to its habit of throwing out one strong shoot, the plant gets lopsided. The long stems, however, are always effective, and the full blooms, which rot before they fall to pieces, are as beautiful as the pointed bloom. It is fragrant, but not strongly scented.

Betty Uprichard seems to combine all the points of a perfect garden rose, with one solitary qualification—that it is not profuse enough, though perhaps we are getting unjustly critical in our search for the perfect all round rose. Still, if we admit the soft impeachment of greed as regards the number of blooms, we must also concede the fact that every bloom is a perfect one. Curiously there seems little scent in the blooms when on the plants, but it is strong enough when they are cut and taken into my lady's boudoir.

At present it can be considered about the most satisfactory all round rose, a good grower, well shaped plants and blooms and good scent, all of which points are confirmed by the R.H.S. bestowing on it about the first of its highest awards after testing it in the Wisley Gardens.

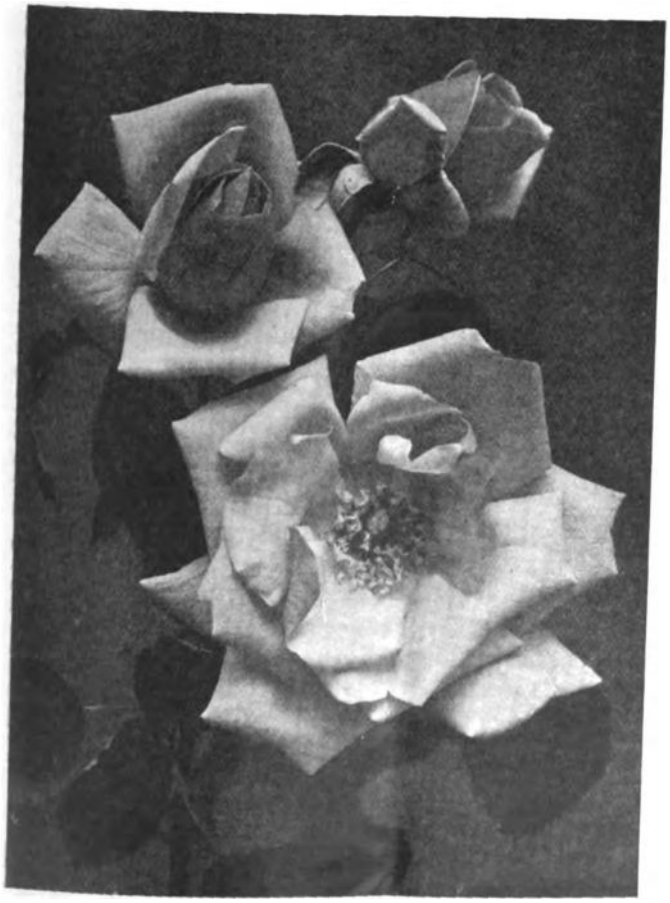
Our American cousins, always most thorough in their methods of judging roses, have divided their "pointing" up very systematically as follows:

(A) Individual qualities. (1) Novelty; (2) Colour; (3) Fragrance; (4) Lasting qualities.

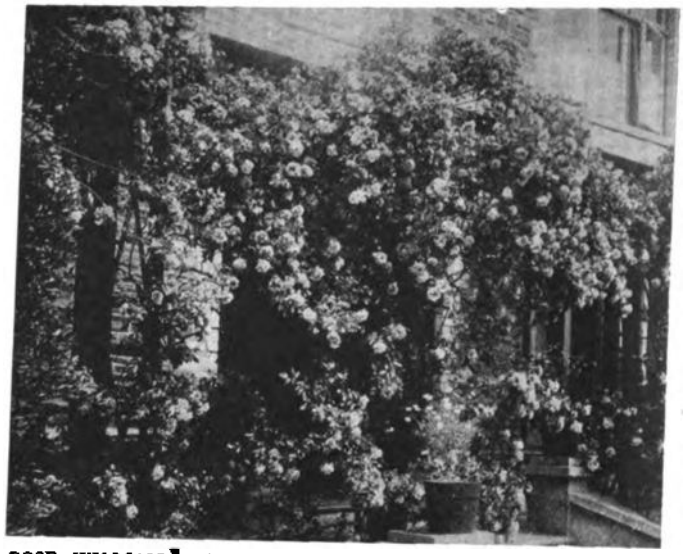
(B) The blooms. (1) Shape; (2) Substance; (3) Petalage; (4) Size.

(C) The Plant. (1) Continuity of bloom and number produced; (2) Hardiness; (3) Foliage; (4) Growth (vigour, uniformity, etc.); (5) Length of stem.

Putting our three typical plants to these stringent tests, we should find Mrs. Laing not scoring heavily in colour and continuity of bloom. Mme. Chatenay would fail in growth of plant and fragrance, while Betty Uprichard's only weakness would, perhaps, be in the lesser number of blooms produced—otherwise she would be almost perfect.



BETTY UPRICHARD SEEMS TO COMBINE ALL THE POINTS OF A PERFECT ROSE.



ROSE WILLIAM ALLEN RICHARDSON, A POPULAR CLIMBER IN THE 'NINETIES.

These three typical roses were selected as being really good roses, well tried and well known, and the writer ventures to predict that in another decade Betty Uprichard will be more popular than it is to-day. Mme. Abel Chatenay will be dropped owing to its faulty growth, while Mrs. Laing will still continue to be grown "for auld lang syne," even though its popularity may have declined.

In recent years there has been a growing agitation against the new scentless roses put on the market, and various efforts have been made with the object of trying to stimulate growers to produce new roses with at least as much scent as the old-fashioned varieties. For many years Messrs. Clay, the renowned fertiliser firm, have offered a cup for competition at the R.H.S. for the best new rose with the old fashioned rose scent, and now the British rose world is agog with the offer of the *Daily Mail* to put up a £250 cup for the best new scented rose.

To a great extent, scent has been far too much ignored by raisers in their efforts to produce new roses of good size and good shape—large blooms, in fact, which were all in vogue when exhibition roses in boxes were the rage.

Fragrance never had the slightest consideration, and this is borne out by the scant references to scent in the rose publications of the 'nineties. As quite a natural consequence, a reaction has come about because too many scentless roses were being produced and were receiving the highest awards. One has only to visit a rose show to watch the disappointment of visitors who, when inspecting boxes of roses, finishing up with a sniff, and passing along to the next exhibit, look back with a dissatisfied remark of "No Smell." Exhibitors and officials of rose shows will have observed this little performance repeated again and again, but now, with the encouragement that is being given by such special and valuable awards as Clays' and the *Daily Mail*, greater attention must be given to fragrance by raisers of new roses.

With the greater prominence given to fragrance, the huge scentless roses are passing away in favour of sweet-scented decoratives, and more attention is given to varieties that will continue to give blooms right up to the approach of winter.

Single roses, which were almost despised a few years ago are now becoming popular on account of their decorative qualities, as witness Dainty Bess, the gold medal rose of last year's Summer Show—the daintiest single flowering rose that has been introduced for many years, and sweet scented withal.

So closes a brief rose retrospect, which is, perhaps, more truly a rose rumination set agoing by a visit to the last great Chelsea Show, but your ruminant is only too well aware that to those who love them, all roses are beautiful—old or new, single or double, fragrant or scentless, wild or domesticated.

POT-POURRI and SWEET-BAGS

"OF THEIR SWEET DEATHS ARE SWEETEST ODOURS MADE."

WHEN what we now know as pot-pourri first appeared in recipe-books—which was not until far on in the nineteenth century—it was under the plain, sensible English name of sweet-pot or sweet-jar, and a good many years elapsed before this was superseded by the unpleasant French one which means, of course, nothing more nor less than "rotten-pot." The oldest directions for the making of a sweet-pot which I have come across, so far, is dated 1790, and the ingredients include roses, orange blossoms, clove gilliflowers (which we call pinks), marjoram, mint, thyme, rosemary, bay and myrtle. These were to be roughly chopped and the finely cut rind of two lemons and half an ounce of pounded cloves allowed to every 2lb. of flowers and leaves. The mixture was to be placed in alternate layers with bay-salt in a big china jar with a tight-fitting lid, and the whole well pressed down. It will be noted that only one kind of spice is given in this recipe, but in others of much the same age mace and cinnamon are added, as well as storax, musk, gum benzoin, civet, ambergris and orris-root. Such potently scented things, however, tend to spoil the natural fragrance of the flowers, and if any pot-pourri maker of to-day is tempted to introduce them she should do so with a sparing hand.

In a recipe written about 1797, the list of flowers includes, besides those named in the one already quoted, fraxinella, violets, syringa, lavender, basil and mignonette, but this last seems an item of doubtful value, as it is anything but sweet-smelling when dead or dying. It might be omitted with advantage, and balm, bergamot, white jasmine and the flowers and leaves (both deliciously fragrant) of the Canadian allspice (Calycanthus floridus) added.

It is obvious that when many different sorts of flowers are used the pot-pourri must, of necessity, be made in instalments. There are two ways of doing this. In the first, which is perhaps the best, the flowers—they must be cut on a dry day and when just fully opened—are chopped up directly they are picked and packed in the jar with the salt and spices, each kind of flower being added as its season comes round and the whole stirred together when the jar is quite full. According to the second method the flowers and leaves are dried on sheets of paper in an airy, but not very sunny, place, and when all are ready, mixed with the salt, etc.; but a good deal of the scent is lost in this mode of preparation. A simple pot-pourri, although one which soon loses its perfume, can be made by blending the flowers and herbs when thoroughly dry, with the spices, but omitting the bay-salt and adding an orange that has been thickly stuck with cloves and slowly dried. Such an orange, by the way, was the original pomander, but the name, in course of time, became transferred to the case—often a gorgeous thing of pierced gold or silver and jewelled or enamelled—which held a ball of scented paste of which the basis was generally rose petals pounded with musk, ambergris, camphor and civet, and moistened with rose-water or blended with wax and, according to some of the ancient recipes, with such strange things as "coales of willowe" and the "maste of a sweete Apple-tree."

The contents of a modern scent sachet usually consist of either lavender alone or cotton-wool sprinkled with one of the strong, coarse perfumes that modern chemists have learnt—unfortunately—to extract from coal "residuals"; but the filling of the sweet-bag of the seventeenth and eighteenth centuries was a far less simple matter. Lavender was certainly used, but invariably in combination with other flowers and herbs and, in most instances, with spices, aromatic gums and citron and lemon peel as well. Cypress and walnut leaves, mellilot and woodruff were sometimes included in the list of ingredients, although few, I fancy, will now be found to agree with Culpepper that mellilot is "well-smelling," for to most people its odour when fresh is positively objectionable. It improves, however, as it dries. Woodruff, which smells like a hay-field on a hot day, was not only put into sweet-bags, but, tied with little faggots, was laid among blankets and woollen garments to keep moths away.

In "The Golden Cabinet," the second edition of which was published in Dublin in 1773, there are a number of fascinating recipes for sweet-bags, the majority being obviously much older than the date of the fat little calf-bound volume. Some are far too lengthy to quote here (one, which the anonymous compiler says will "retain its strength for 20 years," contains no fewer than nineteen ingredients), but here are a couple of the shorter ones:

A SWEET POWDER FOR A SILK BAG.

Take Florentine orris, spikenard, sweet marjoram dried, geranium moschatum of each 4 ounces; damask roses, cypress, lavender-flowers of each 3 ounces; benjamin, lignum Rhodium of each an ounce. Mix them.

A SWEET POWDER TO LAY AMONG CLOATHS.

Take Damask roses dried 1lb.; musk half-a-drachm, violet-leaves 3 ounces, mix them and put them in a Bag.

In all the old recipes for sweet-jars and bags, scented face-washes, perfume-cakes, pomander pastes and the like in which roses play a part, it is always stipulated that they must be damask, often "true" or "right" damask roses. What were these? In one seventeenth century recipe, "red and damask" and in another "red and white damask" roses are mentioned; perhaps the latter was the striped York and Lancaster, although as we know it to-day it is not remarkable for scent! According to Culpepper, "red Roses are under Jupiter, Damask under Venus and White under the Moon" but this piece of astrological information does not help us much towards their identification!

Many—I am afraid most—modern roses are so lacking in fragrance as to be quite useless for pot-pourri or sweet-bags; but Tuscany, La France, Souvenir de Malmaison, Maiden's Blush and the old Moss Rose that was introduced as long ago as 1596, are still with us, and their fragrance cannot be surpassed. Of newer roses, Hugh Dickson is one of sweetest.

There is in "Doctor" Salmon's—I am afraid he had no legitimate right to the title—"Family Dictionary," published in 1696, a wonderful recipe for "Keeping Roses Whole." The flowers were to be dipped in the well beaten white of eggs, "strewn with searced sugar, put up in luted pots and set in a cool place on sand or gravel, then with a fillip of your finger you may strike off the coat and you will have your Flower fresh and faire."

R. E. HEAD.

CORRESPONDENCE

THE HYBRID MUSK ROSES.

SIR,—The varieties classified in many catalogues under the above heading are a very valuable addition to our autumn flowering rose. They are shrub-like in growth and although they will make fine pillar roses, one cannot look upon them as perpetual-flowering climbers or ramblers, which rosarians have long been trying to obtain.

I am very doubtful whether the term hybrid musk is justified. Mr. Pemberton in an article in the Rose Annual for 1926, seems to imply that he has produced a new race, for he says on page 77, "I'll try to breed a race of roses that will give autumn-flowering clusters to carry on the blooming where the ramblers left off and this race of roses has since been known as Hybrid Musks."

Now, in my opinion, the honour for introducing the originals of the group should be awarded to Herr Lambert of Trier, Germany. In 1904 Herr Lambert sent out a variety named Trier which is now catalogued as a hybrid musk. Prior to this, the same raiser had given us Perpetual Thalia, and subsequently Schiller, Heine, Hauff, Adrian Riverchon, etc., all of which were introduced prior to 1913. Mr. Pemberton's first introduction was Danae introduced in 1913, and unless Mr. Pemberton contradicts me I have an idea Danae sprang from Trier.

Now the true old musk hybrids were undoubtedly descendants of Rosa Moschata. Varieties such as River's Musk, Eliza Nerry, Princesse de Nassau, Pissardii, etc., and were autumn flowering, but I question whether any are now in existence, although I believe I saw a bush of River's Musk at Wisley last year.

If my surmise is true that Danae sprang from Trier, then it cannot strictly be termed a hybrid musk, for Trier was produced from Aglaia × Mrs. Sharman Crawford. Aglaia was raised from Rosa multiflora × Rêve d'Or. Can it be that the old noisette Rêve d'Or has bestowed upon its offspring the perpetual flowering habit of the noisette rose, if so, the correct term would be hybrid noisette for the group.

I have no desire to decry the many beautiful productions of Mr. Pemberton, for I cherish them very much. Moonlight, Pax, Clytemnestra, etc., are very lovely and I can well recommend them. I have had these roses make huge bushes planted in isolated positions, and very picturesque they are in the garden or shrubbery.

It would, however, be interesting to learn, if the true old musk roses have produced by crossing any of these varieties, so that we

Digitized by Google

may know if the term hybrid musk is correct. Personally, I am not a stickler for terms regarding various groups. I would call them all "Hybrid Roses," as in fact they are, and likely to become even more so as cross fertilising goes on. Sufficient for me is to obtain the glorious perpetual flowering shrub roses that make our gardens gay in autumn.—WALTER EASLEA.

PLANT NOMENCLATURE.

SIR,—Regarding "F.R.H.S.'s" remarks on page 288, I do not think I have altogether broken the rules, as I propagate all the forms of my pink Primula pulverulenta vegetatively as well as from seed, and I am sure that seed would come true if the plants were isolated and under control, but from a commercial point of view this has never seemed necessary and the various shades of pink appear more effective in mass than when kept separate, hence my allowing the bumble bees to do as they like.—G. H. DALRYMPLE.

FEIJOA SELLOWIANA AS A FRUITING SHRUB.

SIR,—Twice recently I have seen notice in THE GARDEN of Feijoa Sellowiana, and each time it is mentioned as a shrub pure and simple. Out here it is grown primarily as a fruiting plant, and I have been wondering if it is possible to fruit it in England. We regard the feijoa as being every bit as hardy as an apricot or a fig. The flowers come in May, and the fruit matures in October or November—a rather long time perhaps. But it is well worth taking pains over—that is, if one owns a good variety. The seedlings vary much, and one often meets with people out here who say they are unable to get any fruit. So the English climate may not be to blame, but unsuitable varieties.

One curious feature of the feijoa is that the flower petals are quite sweet and edible. In fact, they are recommended for salads. The mocking-birds are especially fond of these petals; I have often been scared for my crop, but they do no harm. Perhaps the birds, flapping among the branches and pulling at the petals, serve to shake the pollen about.

The fruit needs thinning if one is to get it as big as a turkey egg. Most of the fruit made into jam is no larger than a walnut, and the inside only is scooped out. The feijoa seems to be immune to every insect pest.—O. T. BRYANT, *Fillmore, California.*

ANCHUSA MYOSOTIDIFLORA.

SIR,—I was interested to see that "A. H." recommended a south wall for Anchusa myosotidiflora. In this garden it seeds like a weed and comes up in a variety of positions. But nowhere is it finer than in a damp border backed by bushes and on heavy clay. It is a mass of blue, individual heads measuring well over 2ft.—E. M. L., *Leeds.*

THALICTRUM DIPTEROCARPUM.

SIR,—I am delighted to see that a little space is being devoted to "Worthy Plants," and to see that the beautiful T. dipterocarpum has been mentioned under this heading. Here, to my mind is one of the best perennials ever introduced and last year in various parts of South Wales it was splendidly shown by Messrs. Treseder of Cardiff. At our own village show it caused quite a lot of interest. It is one of Veitch's of Chelsea introductions from China, and it grew in their Langley nursery 5ft. and 6ft. high, yet it was graceful in habit, while the branched spikes of lilac-mauve flowers were a sight to behold. Since Veitch's have finished no firm appears to possess the foresight to show it in tip-top condition, but here is a plant of the first water for August and September exhibition. There can be no question of its hardiness or perennial character. For eight years I have had a few plants which flower annually, and now they are pushing up some stout spikes for the ninth year in succession. No doubt a deep rich loam is ideal, but good plants can be obtained in any ordinary flower border. My own plants are examples of the latter. T. dipterocarpum is easily raised from seed sown now and they will germinate either in the open or in pans of light soil placed in a cold frame. If kept growing many of them would flower next year. Another fine thalictrum is T. Delavayi, but, alas! this is now rarely seen. Why is it?—T. W. BRISCOE, *Chepstow.*

THE FIFTY BEST ROCK PLANTS.

The Beauty of Onosma.

SIR,—In the list of the fifty best rock plants chosen by Dr. Lloyd Praeger for "the rock gardener who likes the best, is willing to give time and take trouble with difficult things, has enterprise and an eye for *daintiness* as well as showiness, and is not disheartened by occasional funerals," will be found the name onosma. It occurs in the two lists, though it is not the same species in both of them. Onosma is an interesting plant for several reasons. First of all its name which, being interpreted, comes from two Greek words *onos*, an ass, and *osme*, smell, and was given to it, so we are told, because scent of the flowers was supposed to be grateful to that animal. Then there is the tubular shape of the flowers like those of the heaths and our native confrey to which it is obviously related. It is, moreover, very graceful in its habit of growth, forming nice neat little tufts from which the flower stems spring. These bend over at their ends and it is here that the flowers are collected in pretty pendent bunches like keys on a ring. There are several species in cultivation, most of which come from southern Europe, though one or two hail from farther afield, the Himalaya and Persia. The particular species one generally sees in rock gardens is called echioides or sometimes tauricum, the latter name giving a clue to the locality whence it is derived. This species has been in cultivation in this country since 1683 and has been given the very suitable name of Golden Drop, from the form and colour of its flowers, which have the additional attraction of being almond scented.

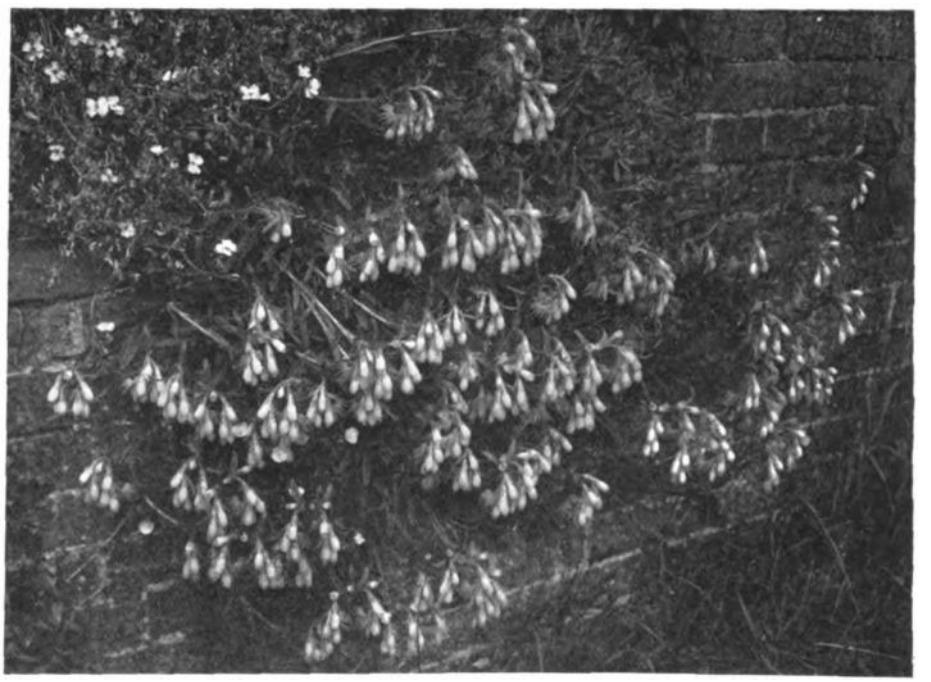
The whole plant is very hairy and the leaves are of a greyish green, forming just the right setting for the golden flowers.

Blooming in June when many of the early spring rock plants are past their best, onosma is a welcome addition to the rock garden. It is not a very fussy plant, but coming from sunny Greece it requires a good sunny position on the rockery to make it feel at home. It also has a rather pronounced aversion to excessive moisture and for this reason it is as well to plant it where an overhanging rock can keep the moisture off without shading it from the sun. In such a position its pendent golden drops show off to the very best advantage.—EDWARD CAHEN.

AN EDGING PLANT.

SIR,—Some years ago we used an edging plant which we used to call "Abyssinian nettle," of which there were two varieties, silver and green and golden, the latter the more effective. It had a small nettle-like leaf, and made nice compact clumps. I believe it had a tiny mauve nettle flower, but think this used to be picked off to keep the foliage a better colour.

I have not seen this plant used lately, and wonder if any of your readers could give me the proper name. I do not find anything like it in my books.—H. JOSEPHINE MEDLEY.



THE BEAUTY OF ONOSMA TAURICUM CAN BEST BE APPRECIATED WHEN THE PLANT IS GROWN AGAINST A WALL.

PRUNUS PISSARDII.

SIR,—I enclose a branch of Prunus Pissardii, with fruit. The whole bush—a large one, 15ft. in height, with a trunk 1ft. in diameter—is similarly laden and I should be glad to know if any of your readers have had a similar experience. I have never previously seen more than a few berries on this shrub.—A. GLADSTONE, *Freshwater, Isle of Wight.*

[The branch sent in was as completely laden as we have ever seen in any cherry. P. Pissardii so far has not been noted for its fruiting qualities; no doubt this is largely a matter of age.—ED.]

GARDEN TECHNIQUE

FLOWER GARDEN

TOP-DRESSING OF LILIUMS.

THERE are several ways of doing this work and the operator should first have a clear idea of why it requires doing, and the nature of the material to employ. Leaf-mould, peat, farmyard manure and loam are all very good for this purpose. Liliums which only have underground roots will seldom require more than a slight covering round the stems of such material as rough leaves, peat or lumpy loam, whereas those which send out roots above ground as well as below, require something more substantial in the way of plant food. Well decayed farmyard manure is best, which may be mixed with rough leaves or peat. Do not make the mistake of applying a lot of material which will run together and prevent the air from reaching the roots of the plant. It is far better to put a little round the plants at intervals rather than sufficient to last the season at one operation. Lilium candidum (the Madonna lily), L. Chalcedonicum (scarlet Turk's cap lily), L. croceum, L. tigrinum and L. testaceum, are benefited by a top-dressing of rough leaves, peat or loam, while L. auratum and others appreciate some good rotten manure mixed with lumpy loam. If due attention be paid to this important point of cultivation many liliums which otherwise could only be planted in damp situations will make a brave show in the border even if they be exposed to the sun, so that position becomes a secondary consideration. I well remember seeing and admiring a bed of the beautiful Nankeen lily (L. testaceum) flowering profusely in a round bed situated in the centre of a garden. Here the owner had afforded protection to the roots by judicious top-dressings—F. K.

VIOLAS.

Topical Cultural Notes.

IT has become proverbial to say of some plants, that they flower themselves to death if you only let them. Violas are a typical case, and it, therefore, behoves all who have them under cultivation to do all that is possible for them during their season of blooming. Some of them are at the zenith of their beauty; young plants more particularly, which are possessed of greater stamina than old clumps, but both will continue to respond freely if one can give them daily attention. This involves the cutting off of all dead and dying blossoms, and preventing seed pods forming; in watering them freely at night during a hot dry period, and in conserving the strength of the plants by applying mulchings about the roots. This may be in the form of old, rotted manure, or leaf-mould. Sometimes, too, where many plants are grown, it pays to give them a forced rest by denuding them of every bud for a week or two. They will respond afterwards with greater vigour as if grateful for freedom from production of blossoms. It is an experiment that anyone can make, and I have never found it to fail.—CLAREMONT.

CUTTING BACK PYRETHRUMS, DELPHINIUMS, ETC.

OLD plants, after they have flowered, are, in the majority of our gardens, cut back with a view to tidiness of border. But cutting back plants after they have borne their first harvest of flowers should be work well done, and with a view to a second crop of flowers as well in the interests of tidiness of border. Thus two purposes are served. The second batch of flowers, like that of roses, is often composed of very neat, highly coloured, refined blossoms; they are splendid for cutting and placing in vases, while in the borders they prevent a blank. In the case of delphiniums the cut-back plants afford us a fine display of blue which is often lacking late, or even early, in the summer.

The pyrethrums are now, in June, at their best in most gardens and, although they continue to yield odd flowers for a long time, a better and fuller succession can be obtained by judicious pinching or cutting back. If an autumn display is required, cutting back will afford the best results. Before making use of the knife, closely observe the foliage near the base of each plant and preserve as much of it as possible, cutting away the old flower-stems and the more seared inside leaves. The retained main leaves will add strength to the resultant new growth, including the flower-stems. Practically the same course should be taken in dealing with delphinium plants. Do not cut any of the old stems down to the ground level but several inches above it. Gather up the retained outer leaves carefully, remove any very loose soil from the surface close to each clump, and have in readiness some good loam and rotted manure to replace it forthwith. Failing manure, give a thorough soaking with manure water.—HANTS.

PROPAGATION OF PERENNIALS.

Raising Herbaceous Plants from Seeds and Cuttings.

THIS is a very interesting occupation, which may be carried out in some form or other practically at all times of the year. The stock of plants may be increased successfully by means of seeds, cuttings or division of existing clumps. In many instances seed cannot be relied upon to produce plants of the same colour as the parent, but many people deem that an advantage, as being more interesting. Broadly speaking, all seeds of perennials may be sown in May, and will flower in their season during the following year or two. Michaelmas daisies, phloxes, Chrysanthemum maximum, delphiniums, gaillardias—to name but a few—will all flower the same year if sown early in heat. It may be taken as a general rule that all boxes or pans used for seed raising should contain a lighter mixture of soil than the plants require when finally planted out. Boxes and pans should be made up with a level soil surface, and should be given a good soaking before any seed is sown. Use, if possible, fresh loam and clean sand, as it is unfair to blame the seed if failure occurs through attempting to raise seedlings in old potting soil which is probably sour and has a certain amount of artificial manure in its composition. Cold frames are better than greenhouse shelves at this time of the year for seed raising, but they should be situated where they will receive a fair share of sunshine. If the latter should prove too strong, it is an easy matter to shade. The little seedlings will require transplanting as soon as they are large enough to handle. Generally speaking, avoid a position in full sun for this operation; one which is slightly shaded is to be preferred, as the plants will require less care in the way of watering, and will go ahead better. In many cases it is an advantage to have the plants in their permanent position in the border by autumn. The amateur will find it a difficult matter to find cuttings on many classes of herbaceous perennials during the summer months, but still there are plenty of dwarf plants employed in rock gardens and the edges of herbaceous borders which yield suitable growths for cuttings. In most cases cuttings taken of double arabis, aubrietia, Phlox subulata, the trailing veronicas and such-like plants root readily if placed around the edge of a pot. Use a broad-ended dibber and see that the base of the cutting rests on the soil, which should be of a sandy nature. Plunge the pots up to the rim in fine ashes, well water the cuttings and keep the frames closed, taking care to shade, if necessary. When rooted, admit air gradually and discard shade.

Division can be carried out in spring or autumn. Phloxes, Michaelmas daisies, delphiniums, aconitums and others are best divided about every third year. Do not attempt to chop the clump into chunks with a spade, but use a garden fork. The result will be much better, as fewer roots will be damaged. Plant the outer portion of the clump, discarding the original centre, which will be worn out. I think this mode of cultivation is fairly well understood by the majority of gardeners, therefore little need be said on the subject.—CUMBERLAND.

POLYANTHUS FROM SEED.

POLYANTHUS seed germinates readily if sown as soon as ripe. Unless a particular colour is required, an abundance of seed may be collected from the finest plants in the beds, but if we desire a colour scheme and must have plants true to colour, it is better to obtain seed from a reliable seedsman and be reasonably sure of good results. I consider it sound practice to sow the seed in boxes or pans of prepared soil, covering the seed with fine sandy soil and place in a cold frame. Always give the soil in boxes or pans a good watering before sowing. Cover the box with a piece of glass and shade with paper until the seedlings appear. When the seedlings are up, remove the glass and the shade will only be required to prevent the sun scorching the tiny plants. If the soil in the box should appear dry, give a good watering, choosing, if possible, a sunny day so that the foliage will get dry as quickly as possible, as damp foliage often causes "damping off." For a short time a little shade may be necessary during the day if bright, sunny weather be experienced or if the frame be fully exposed to the sun. Carefully harden off the seedlings, admitting a little air daily, increasing the amount until the lights may be left off day and night. When the seedlings are large enough to handle, a piece of ground should be selected which is partially shaded and the seedlings transplanted about 6ins. apart. Dust round about the plants some old soot; it may keep off an occasional slug, and at any rate will stimulate the plant. They may require attention during the summer, but nothing more than a drink of water and the hoe run through the rows. There are some districts where plants raised from a summer sowing do not make good plants the following year. A good plan is to sow during February in boxes or pans, placing same in a warm greenhouse. This will give the plants a much longer season of growth, although the seed may not germinate as quickly. Always endeavour to prick off a certain number of the smaller seedlings, as they very often prove to be of finer colour than the more robust ones, the latter at times being rather coarse in flower. The object of this note is to remind garden lovers that the time for seed sowing is at hand.—F. C. KING.

FRUIT AND VEGETABLES

BIRDS AND SOFT FRUIT.

WHEN the soft fruits are ripening, care should be taken to protect them against the attacks of birds. Blackbirds and thrushes are particularly prone to sample strawberries,

Digitized by Google

currants, raspberries and cherries. Sparrows will attack almost anything and are often the cause of much damage to ripe gooseberries. Netting is, of course, an effective way of keeping the marauders at a distance, and, failing proper nets, old window curtains are by no means to be despised. Even if the curtains do not cover the whole of the bush, they will often frighten the birds so that they remain at a respectful distance. A very good protection for strawberry beds is the running of lengths of cotton between short stakes over the plants. All birds are desperately afraid of cotton, and, after one attempt to get at the fruit, will not come again. Strips of material that flutter about in the wind may also be used with good effect on bushes and small trees. If these are blue in colour so much the better. For some reason which has not been explained, all birds are distrustful of anything blue, and even bits of blue paper are useful if cloth cannot be obtained. In more than one garden with which the writer is familiar, the soft fruits have been saved by the simple plan of supplying the birds with water. There is no doubt that blackbirds and thrushes peck at the fruits because they are thirsty. Always the greatest amount of damage is done in dry weather. Large saucers of water placed about the garden will draw the attention of the birds away from the fruit. In fact, the birds seem to prefer to take a drink when they can get it. This does not apply to sparrows, for these mischievous birds will attack anything and everything, apparently with the desire of doing as much damage as they possibly can.—S. L. B.

THINNING APPLES.

This will help the Formation of First-class Fruit and Prevent Overbearing.

SOON we shall be busy thinning the fruits of apple trees. Some of our varieties did not bloom so freely as last year, and a few, such as Cox's Orange Pippin and Allington Pippin, will not require any thinning, for the fruits are already quite thin enough.

However, every tree which sets a good crop is always thinned here, and from past results it certainly does pay to spend a little time on this very necessary operation. I know that it seems wasteful to go over a tree which has set a large crop and pull off two-thirds of the fruitlets. The result of this thinning is that we get very few third grade fruits, a few second grade and a very large proportion of firsts.

We commence thinning the fruits as soon as they have started to swell, so that we are sure the fruits we leave have set properly. With our trees, which are well spurred, we find we have enough fruits on each tree if only one fruit is left on each spur. Of course, this operation is not a rule of thumb job, but one which must be done carefully and thoughtfully. To obtain a full crop it may be necessary to leave two fruits on some spurs, while in other cases it would be better to take every fruit away from a few spurs.

As for the manner of removing the fruits, we simply pull off those not required, at the same time removing a leaf or two if it seems likely that the leaves will shade the fruit too much. This latter is a point well worth noting by those who appreciate colour in apples and admire those highly polished American apples which are to be seen in our shops. We can get colour in our apples in most seasons, as witness the fruit exhibited by English growers at the Imperial Fruit Show.

I was once thinning some trees of Cox's Orange Pippin which had set an enormous number of fruits. I pulled off so many fruits that I got alarmed merely as a result of looking at what I had pulled off rather than at what I had left. Eventually I left more than I should, not more than the trees could carry, but more than they could bring to perfection, with the result that we had to market a lot of second grade stuff.

Stirling Castle, usually the most regular of croppers, was another variety which was not sufficiently thinned. We had a huge crop of first-class fruit, but the trees are exhausted and are taking a rest this year.

We hear a great deal about biennial bearing of apples, and various remedies are put forward from time to time. In my opinion, proper thinning of the fruit will go a long way towards making trees annual instead of biennial bearers.—N. D. H., *Warwickshire*.

BUSH FRUITS AND STIMULANTS.

ANTICIPATIONS aroused by promises of good crops on currants, gooseberries and raspberries, are sometimes doomed to disappointment on the approach of dry weather, when fruit suddenly ceases to swell and drops off, if steps are not taken to avert it. Not infrequently, it is the last efforts before gathering crops which determines the extent of the reward. If the hoe was used between the trees in spring and subsequently, the rough soil will to an extent prevent evaporation, and it can now be followed up by mulchings of any old manure available, leaves, or spent hops; indeed, almost any rotted vegetable matter that will help to conserve moisture. Especially does this apply to raspberries, the roots of which lie near the surface, and, sooner almost than any other fruit are the first to feel drought. Just now, too, much may be done for bush fruit trees by feeding them with liquid manure made from cow or sheep dung, if procurable, but in no case ought liquid manures to be given in dry weather until after the trees have had a good soaking of clear water.

A thorough drenching with water at night if the ground is very dry will do a deal in preventing fruit dropping, and nothing appreciates moisture more than raspberry canes. House slops, diluted, and soap suds, should not be poured down drains, but used among the fruit trees.—CLAREMONT.

PLANTING BRUSSELS SPROUTS.

TO produce erect plants of this vegetable, covered with tight, compact buttons, planting in firm, rich ground and a long season of growth are necessary. Planting out should take place during June. Lift the young plants carefully from the nursery bed with as large a ball of soil as possible, and plant them at once in firm ground, placing them 2ft. apart in the rows and 3ft. between each row. If the ground is at all soft, make it firm by treading before planting is carried out. When the plants are established, feed them at regular, but not too frequent, intervals by means of a light dose of nitrate of soda or a complete fertiliser.

VEGETABLE MARROWS.

YOUNG plants of vegetable marrows should be hardened off for several days, and then planted in their permanent quarters. A cold frame over an old hot-bed, or a prepared bed in the open, is a suitable position.

VEGETABLE MARROWS GROWING IN A RAISED BED IN THE OPEN.

The compost in a frame should be light and rich, and the plants should be at least 4ft. apart. In the open, marrows can be grown on raised heaps or in sunken beds. The latter is in some ways the better method, as the soil does not dry out during excessively hot weather. In either case the bed should be about 2ft. deep, the bottom consisting of a mixture of rotted manure, decaying vegetable rubbish and leaf soil, and the top of fine, fairly rich soil. For the first week or so after planting, protection from late frosts, strong sunlight and cold, cutting winds will be necessary. Slugs are liable to damage the young plants, and so should be guarded against by sprinkling sifted ashes round each plant, dusting with soot or sanitas powder. Watering should be attended to regularly and, when a number of the flowers have set, an occasional application of liquid manure is most helpful. The main stem should be pinched out when about a yard of growth has been made, and only four or five lateral growths should be allowed to develop, but these must never be pinched.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

THE FLOWER GARDEN.

In some gardens a quantity of such plants as double arabis, aubrietia and forget-me-not, are required for beds and borders, also as a groundwork to tulips and other bulbous plants. Now is a suitable time to propagate such subjects, and if the arabis and aubrietia have been slightly cut back after flowering, there will be plenty of young shoots suitable for cuttings. These will root readily in a cold frame or hand light if set in sandy soil. The myosotis can be raised from seeds sown during the next week or two. The small flowered rock garden and border candytufts, such as Iberis sempervirens, can also be increased by cuttings with arabis. Polyanthus are indispensable spring flowers, and it is at this season that a sure foundation is laid for next year's display. The seedlings are set out in lines 1ft. apart, for preference in a partially shaded spot, and kept free from weeds by occasional hoeing. Old plants can be divided into single crowns and treated the same as seedlings.

Double Daisies, white and coloured forms of Bellis perennis, are excellent for spring bedding and now is the best time to increase the stock by division. Sweet peas as they reach the flowering stage should be afforded a mulch of manure between the rows, and the roots fed with liquid manure or a special sweet pea fertiliser. Do not allow seed pods to form, or the plants will soon lose vigour and cease blooming.

THE FRUIT GARDEN.

Morello Cherries.—These useful fruit trees need somewhat different treatment from the sweet varieties, and from now onwards they must have attention in thinning and tying the shoots in in accordance with the requirements of the tree. Sufficient young growths are retained to carry a crop next year, the surplus shoots being carefully pulled out at their base, and care ought to be taken to avoid overcrowding. No stopping is needed, and if the growths are tied in position more light and air will reach the fruit. Specimens producing heavy crops will benefit by an application of liquid manure diluted to the colour of straw, say once a fortnight, until the fruits begin to colour. A mulching of manure is also recommended. Keep the trees free from aphis while the fruit is still green.

Gooseberries.—If choice fruits are desired for dessert in August, the crop must be reduced, and, fortunately, the green fruits can be used for preserving. A mulch of partially decayed manure will help to produce fine fruits, especially if water is given during a dry period. Cordon and standard trained trees will need attention at this season. All side growths are pinched back to four or five leaves, and all basal shoots, viz., at the ground level, are removed. The main shoots are allowed to extend, these being tied to the wall or other supports. With the selection of suitable varieties, and planting cordon trained trees in different positions, the supply of ripe fruit is extended over several weeks. Moreover they are more easily protected from birds.

THE KITCHEN GARDEN.

The early sown leeks will be ready for transferring to their final quarters, and unless exhibition roots are required, there is no need to make elaborate preparation for this crop. The lines should be 15ins. apart and the plants about a foot. Holes 12ins. or so in depth can be made with an ordinary crowbar, and the plants just dropped in. Subsequent hoeing will eventually fill the holes as the plants develop.

Celery trenches should be prepared and a liberal quantity of manure placed at the bottom, as celery is a gross feeder. A space of 4ft. is allowed between the trenches and 9ins. between the plants. Plenty of water is needed if the weather is dry, and if the maggot appears in the leaves, spray with a solution of quassia extract. The white variety of celery is planted out first, followed by the pink and red kinds.

Chepstow. T. W. BRISCOE.

FOR NORTHERN GARDENS.

THE KITCHEN GARDEN.

The main batch of celery will now be fit to plant out. To delay this beyond a reasonable limit is courting failure in the initial stages because of its proneness to "bolt" if given a check through lack of moisture or other mismanagement.

Lift the plants with a good ball of soil attached, remove all side shoots and decayed leaves, plant carefully and firmly, watering in as the work proceeds. Afford shelter and shade until the plants become established by placing a few spruce branches over the trenches. Good culture at every stage of growth is necessary, with abundance of moisture and liquid manure.

Repeated dustings of soot or spraying with paraffin emulsion will prevent the celery fly from depositing her eggs on the leaves. If celery leaf rust has been troublesome in previous years, spray early with Bordeaux mixture or liver of sulphur.

Celeriac in its early stages requires much the same treatment as celery, but later the culture is quite different. Choose a soil light and rich and put out the plants on the level 18ins. apart each way. Plant as shallow as possible, removing all lateral shoots to prevent division of the stem. Later cultivation consists in keeping the ground clean and frequently removing the soil from around the bulb, watering if needful to ensure them attaining a good size.

Lettuce and other salads should be sown frequently. Before planting the celery the top of the ridges will provide space for transplanting of lettuce and sowing of seeds for successional crops of these. At this season lettuce will probably do best if sown where they are to mature.

Sow turnips for late supplies, choosing varieties of the Stone or Golden Ball type.

To provide salading in the autumn when lettuce are not so plentiful make a first sowing of endive. Use the broad and curled leaved varieties, both useful in different ways, sowing the former in drills 15ins. apart, and the latter, not so robust in growth, 12ins., thinning to 12ins. and 9ins. in the rows. Transplant some of the thinnings, as these, coming in a week or two later, will make a succession.

For the above reasons, and as affording variety, sow corn salad now and later. Ordinary soil and open aspect will suit meantime. Thin out seedlings 3ins. to 4ins. apart and the lines 6ins. to 8ins. asunder.

Asparagus beds still bearing should be kept free from weeds and have weekly dressings of nitrate of soda, 2 oz. per square yard, or applications of liquid manure, to supplement the chemicals, superphosphate and kainit, applied in March. Support the green growth with pea sticks to prevent damage by wind.

Early cabbages and cauliflowers are benefited by having some soil drawn up to the stems. This gives support to and induces or encourages the plant to form new roots, so helpful if enfeebled by the attention of the larvæ of the cabbage fly in the early period of growth. Liquid manure will be appreciated if given on this and later occasions.

Cultivate between the drills of late potatoes and earth up as required. As this crop is the one usually attacked by the potato blight disease, the possibilities of preventive spraying with Bordeaux mixture are worth consideration.

Under normal conditions the crops may now be left to take care of themselves to some extent, and while this may lessen the gardener's anxieties, yet his activities must not cease.

GENERAL WORK IN THE GARDEN.

In the period involved by bedding out and planting the kitchen garden the amenities of the gardens and grounds will have been partly neglected.

Drives, avenues and walks will require the edges clipped and brushed up, assuming that the weed-killer applied in May has been effective. Gravel walks should be raked and rolled to renew their freshness.

Boundary grounds also should be attended to. Cut rough herbage which forms a shelter and host for numerous fungoids and insect pests. Nettles, if cut regularly for a number of years at certain times, will disappear. Colonies of dandelion, docks, etc., are cheaply got from this source, but expensive to get rid of.

Doune, Perthshire. W. MCCARRELL.

CUCUMBERS IN FRAMES.

A week in advance of putting out young cucumber plants make up a bed of strawy manure, augmented with leaves and lawn mowings if necessary. Consolidate the bed as the work proceeds. Make the bed a foot wider than the size of the frame and use the fermenting material at the rate of two cartloads for every frame light.

Place a barrowload of good compost, consisting of loam with leaf-mould and sand added to ensure porosity in each light and close up the frame. When the heat is steady, averaging 60° at night, the plants can be put out with safety. Give a little shading, gradually reducing this as the plants gain in strength. Syringe the plants and sides of the frame frequently with water at the same temperature as the frame.

Give water only when required, and then in sufficient quantity to soak the growing medium thoroughly, and as soon as the plants have made three rough leaves pinch out the points.

When the shoots accruing from the first stopping have made four rough leaves pinch out the points of these. This will be enough stopping until a show of fruit is seen, spreading out the shoots to cover the space, afterwards pinching the fruit-bearing shoots at two leaves beyond the fruit, thinning out superfluous growths.

Red spider and thrips are the worst of all pests the cucumber grower has to contend with. Avoid a too low temperature with draughts, such conditions being responsible for the appearance of mildew. Should such appear, remove badly infested leaves and dust with flowers of sulphur.

CUCUMBERS IN THE GREENHOUSE.

The cultivation of cucumbers in greenhouses differs only in detail from that of growing them in frames.

Withhold a portion of the material used in making up the bed in frames. Place it over slates or a grating situated just above the hot-water pipes in the house selected for growing the cucumbers. To begin with, place a bushel or so of good compost under each light or in a continuous ridge along the bed. To warm up the soil turn on the heat and let the temperature run up fairly high for a day or so, and then put out the young plants.

Support the young plant with a stake until it reaches the first wire. The plants should be allowed to reach the topmost wires before pinching out the tips. Train out the side shoots to the lower wires as they appear, stopping them one or two leaves beyond the fruit. By this time it may be found that, by judicious management of airing and shutting up, fire-heat may be dispensed with except in very cold and wet spells.

MELONS.

To grow melons in frames the hot-bed should be formed as described for cucumbers. Use, if possible, a three-light frame to secure a more constant and regular heat. Melons differ from cucumbers in requiring more light and air, a heavier soil, less water and a higher temperature.

Make up a ridge of loamy soil with old lime rubble and wood-ashes added. And when the heat of the frame shows about 65° to 70°, put out the young plants, one to each light. Shade the plants a little until growth is active, ventilate the frames when 80° is registered during the day, water carefully and syringe frequently in sunny weather.

The melon plants from the March sowing will be swelling their fruits, and should have all unnecessary growth cut away.

Give top-dressings of good loam as a rooting medium for the thick white roots showing on the top of the bed, making this firm as before with a rammer. Feed with liquid manure, ringing the changes with artificials. Close down the ventilators early in the afternoon, syringing and damping down frequently, maintaining a night temperature of 65° to 70°.

The young plants from the sowing made early in April should now be planted out from the 5in. pots to their permanent quarters in the melon-bed. Fill up the bed with fermenting material, stamping it firmly to discount shrinkage later. The compost should be placed in small mounds about 2ft. to 3ft. apart on the bed and left for a day or so to acquire the same temperature as the house. Allow one plant to each mound, ramming the soil firmly when planting, and stake the plants until the first wire is reached.

MISCELLANEOUS NOTES

FINAL POTTING OF TREE CARNATIONS.

CUTTINGS rooted late last year and also during the past spring will be in good condition for the final potting now if the young plants have received proper treatment in the meantime. Plants that were stopped low down—and not merely topped—will now possess from three to six strong side shoots, according to individual strength. Now, the final potting does not mean shifting the plants to very large pots, especially those plants resultant from late-rooted cuttings. Pots measuring 6ins. across should be the largest used for such. Many cultivators flower their plants in 5in. pots, but high feeding is necessary and, generally, skilled treatment, and as my hints are for the benefit of those who have not had much experience the 6in. pot will afford the best results. The pots should be very clean, both inside and outside, and quite dry when used. For drainage, a lot of crocks are not necessary; use a few only and place them well. One large hollow crock and a few smaller ones will answer nicely. I like one hollow crock and broken bricks for the draining of my pots—old bricks with mortar adhering to them.

The compost is important, but it need not be elaborate or made up of many ingredients. Fibrous loam, in which the grass roots are dead, should form the chief ingredient. The more fibrous it is the better, and it should be pulled into small pieces, otherwise the fine mortar rubble and the bone flour will not be evenly mixed with the loam. Very coarse, dry sand may be used in place of the mortar rubble, but the latter is much the better. A small proportion of fresh leaf-soil will improve a heavy soil compost. Firm potting is essential, but the necessary ramming must be on the new and not on the old, which contains the roots. Space should be left for watering and feeding with artificial and liquid manures, but not for any top-dressing, as this is not needed. All necessary stakes should be put into the new soil at the time of the final potting, then there will not be any interference with the roots later on, as would be the case if the work of staking was unduly delayed. After the potting is finished the plants should be placed again in a cold frame, freely ventilated night and day, and be left there until the end of June. During July and August the best position for the plants is one on a bed of ashes in a quite open quarter outside.—G. G.

MOISTURE CONSERVATION versus WATERING.

EXCEPTING in the case of certain newly planted subjects, such as evergreens, we have long ago abandoned watering as a regular garden practice, and this in dealing with a sharply-drained light soil. As an alternative our principle consists of conserving the natural moisture by checking evaporation. In this there is, of course, nothing new. It is a principle (involving, by the way, less labour and securing better results), that has always been practised by some, yet it is one which is seldom adopted or understood as fully as it might be by the average amateur.

Deep cultivation, including a thorough loosening of the subsoil, is, in the first place, a factor of superlative importance in making the way free for that upward moisture flow which is ever present in the driest of soils. Then comes the arresting of that moisture at or near the surface and this may be accomplished in various ways to suit different phases of gardening. First there is the mulch, usually supplied in spring, and consisting of half-rotted farm manure or decayed vegetable compost, peat, spent hops, sphagnum, seaweed, peat moss litter and the like. The last mentioned, finely granulated and well weathered, is the finest moisture absorbent and retainer I know and it is one of the most durable of all organic substances.

Nature adopts the humus mulch referred to as a moisture retainer, but she attains the same end generally by her carpeting, or sward, of living herbage. This we can often imitate, as on rock garden slopes and ledges, in heather gardens and other places, by keeping the surface well covered. There is a vast number of plants which delight to grow in close association one with another, thus forming a sort of natural turf like an alpine lawn which very effectually checks that evaporation which must rob the roots of most plants isolated on a sun-beaten ledge.—A. T. J.

HINTS ON RHUBARB CULTURE.

WHEN the rhubarb crop is ending it is to be feared that many growers tend to neglect the clumps. Of course, the present is a very busy time and there is much urgent work to do in other directions, but, if a good crop is to be assured next season, serious attention must be given to the rhubarb bed. Generally speaking as soon as the gooseberries come in there is not much demand for rhubarb, but there is always a temptation to pull away the stalks as long as they remain. This is a great mistake for it weakens the crowns and, if persisted in, the crop next year will be poor. The leaves are necessary to carry on the work of the plant and a fair proportion should be left to develop and die off naturally to feed the crowns next yaer. Of course, in the case of newly established beds, it is not advisable to pull any of the leaves or stalks and, even in the second year, care should be taken to leave a liberal amount of leafage to complete the natural growth of the plants. It is not until the third year that a rhubarb bed can really be said to be in full cropping, and, even then, as has been indicated, the pulling must not be too close.

At the end of the pulling season treat the rhubarb plants well. On the bed, weeds are sure to grow apace and these must be kept down or the final stages in the growth of the plant will be seriously hampered. Liquid manure is good for a rhubarb bed at any time, but, most of all, is it of service after pulling has ceased.

When a little time is available this may be usefully employed in loosening the soil of the rhubarb bed. This will help to keep the moisture in the ground and be of great service to the rhubarb, which naturally thrives in rather damp situations. In long spells of dry weather a thorough soaking of water may be given the bed with advantage.

Every rhubarb bed should have an annual top-dressing of manure, preferably given during the late autumn or winter. Even with this aid the production of the bed begins to decline in five years as a rule. The new plants are secured by dividing the root-stocks of the old crowns in the autumn. —BOURNEMOUTH.

SHRUBS FOR THE GREENHOUSE

NOTES ON SUMMER QUARTERS.

THE owner of a greenhouse need not be without flowers and fresh foliage for a great part of the year if he possesses a good collection of flowering shrubs. Only sufficient artificial heat is needed to exclude frost and any excessive damp. This being so, readers will at once realise that many kinds require quite cool treatment, preferably in cold pits or in the open air during the summer months. A great many plants are ruined because they are retained in the glass structure all through the hot days of summer. The attention given should be timely. For instance, rhododendrons and azaleas that have flowered under glass—of course, several weeks earlier than they would in the open air—must be allowed to remain in the structures while they are making new growth, or recovering from being shifted to larger pots. It is also advisable to be very careful about placing the plants in the open too soon for the same reason.

The greenhouse acacias and the genistas flower several weeks later than the azaleas and rhododendrons, and so these must be retained in the structure a little longer. Their position should be a lightly shaded one and the floor and stage near the plants kept moist, to prevent, to some extent, the spread of red spider. In their case it will not be necessary to keep the plants under glass when the flowers have faded; remove them early in the summer to cool quarters outside.

The winter-flowering epacris should be placed in a cold frame facing north during the summer months. Heaths must be kept cool and shaded, whether in the greenhouse or the cold pit, after flowering. The plumbago and bougainvillea, treated as shrubs, should be retained in the greenhouse if judiciously ventilated, where they will thrive in full sunshine. If we class the bouvardia as a warm greenhouse shrub—and it is, undoubtedly—then give the plants frame treatment all summer without undue coddling.– G.G.

ANTIRRHINUMS

IT'S only the fact that we grow and deliver especially good plants that we wish to advertise. The brightness, the long-flowering life, the wonderful adaptability of Antirrhinums (Snapdragons) are known to everyone. Although our plants are properly grown, transplanted, well rooted, hardened off, in all ways particularly good, as becomes a firm which reckon to do things well, the price is only

1/3 dozen. **8/6** 100.

Carriage paid on orders value 5/- and over, otherwise 9d. extra.

And these are the varieties and colours

Codsall Rose, delicate pink
Cottage Maid, pink, white throat
Crimson King, rich dark crimson
Dainty, gold and terra cotta pink
Electra, salmon orange, white throat
Dazzler, orange scarlet
Firefly, scarlet
Glow, orange apricot
Melrose, bright rose
Rose Queen, rose pink self
White Queen, pure white
Yellow King, rich yellow

PROPAGATING GREENHOUSE PLANTS.

IF the greenhouse is to be kept gay all the year round, fresh batches of cuttings of many kinds must be rooted from time to time. Numerous kinds may be propagated in the autumn, but I think the best time for carrying out the work is spring and early summer, and amateur cultivators should not have much difficulty in successfully rooting cuttings. The best general compost for the latter is one made as follows: Fibrous loam, passed through a ½in. mesh sieve, 2 parts; old leaf-soil, also sifted, 1 part; and very coarse dry sand, 1 part. For the benefit of purely hard-wooded kinds, the loam and the leaf-soil should be used in equal quantities. Three-inch and five-inch pots are the most suitable sizes, and a cold frame placed on a stage facing east, west or north; or a slight hot-bed in a frame in the garden will be found best, both under the greenhouse roof or outside, for successful propagation. Cuttings of hard-wooded subjects should be of young wood with a tiny heel of harder wood attached, and the latter should be severed with a sharp knife. Cuttings of soft wooded plants should also be selected from young branches and mostly be severed just beyond the harder, or last year's, growth. Some kinds are persistent in producing flower buds and stems, and so all of these must be removed directly they are large enough to handle. Water will be needed oftener than in the autumn, but over-watering must be avoided. Judicious shading will be very beneficial.—HANTS.

The Perfect Sun Blind for Glasshouses

Cannot rot or perish.
Easily fixed and removed.
Admits ample light.
Economical in wear.

Several thicknesses, from 19/6 mile (full 1,760yds.). Small lots quoted. Post card to-day for free samples and list of 300 bargains.—GREEN'S GOVERNMENT STORES, 355, Albert Street, Lytham.

SEWAGE DISPOSAL FOR COUNTRY HOUSES.—No emptying of cesspools; a perfect fertiliser, no solids; no open filters; perfectly automatic; everything underground. State particulars.—WILLIAM BRATTIE, 8, Lower Grosvenor Place, Westminster.

GARDEN NETS.—Best tanned, small mesh; 25yds. by 1yd., 2/-; 25yds. by 2yds., 4/-; 25yds. by 3yds., 6/-; 25yds. by 4yds., 8/-. Carr. Paid. Satisfaction guaranteed. Tennis nets from 10/-. Special nets for tennis boundary. Pea training nets. Lists and samples free.—G. JARRETT, Netmaker, Rye.

TANNED GARDEN NETTING.—Best selected nets, small mesh only supplied. 50yds. long, 4yds. wide, 14/-; 25 x 8yds., 14/-; 100 x 2yds., 14/-; 25 x 4yds., 7/-; 25 x 3yds., 5/-. Any size to order; all sent carriage paid.—W. GOULDEY, Walmer Road, South Lowestoft.

ROCK AND ALPINE PLANTS.—Large and varied collection. All pot grown. Packed and carriage paid. Catalogue free.—M. J. PIGGOTT, Duffield, Nr. Derby.

TANNED GARDEN NETTING, small mesh: 25yds. by 1yd., 2/-; 25yds. by 2yds., 4/-; 40yds. by 1yd., 3/3; 40yds. by 2yds., 6/6; 40yds. by 3yds., 9/9. Measured mesh closed. Special Pea Netting supplied. Tennis Nets from 8/-. Carriage Paid. Compare our netting with others. Sports lists and samples free.—GALLOP, Net Manufacturer, Hastings.

HERRING NETS, Small Mesh, to protect all kinds of fruit, approximately 80ft x 30ft., 12/6 each. Smaller pieces, 5/- and 6/6, good value. Carriage paid. Cash with order.—WM. G. GRIGOR, Port Gordon Station, Banffshire.

LOOK ! TANNED GARDEN NETS.—All orders dispatched same day. 25yds. by 1yd, 2/-; 25 by 2, 4/-; 25 by 3, 6/-. Odd netting for bushes, 6lbs. for 2/6. All carriage paid. Any sizes supplied. Also Tennis Boundary Nets.—MOORE AND CO., Net Works, Rye.

NATIVE PLANTS FOR YOUR GARDEN.—Write for list of "Wild Garden" and other plants.—NATIVE PLANT NURSERIES, Rockbeare, Exeter.

CISTUS (ROCK ROSE).—Strong young plants from 5/- per dozen.—NATIVE PLANT NURSERIES, Rockbeare, Exeter.

A CATALOGUE of gardening books will be sent free on application to "COUNTRY LIFE," LIMITED, 20, Tavistock Street, Covent Garden, W.C.2.

RARE PRIMULA AND ALPINE SEEDS from large (2,000) collection. Also seedlings and plants. Lists free.—REV. J. F. ANDERSON, Glen Hall, Leicester.

SINKS FOR ROCK GARDENS.—A large quantity of Glazed Earthenware Sinks in various sizes is available for disposal, suitable for use in Rock Gardens, etc.—Apply ROADS AND COMMUNICATIONS OFFICER, Evelyn House, Salisbury.

LEEK PLANTS.—Strong plants of our famous Giant Musselburgh now ready, 1/9 per 100, c.w.o., free by post, low quotations for large quantities. Price lists free.—DICKSONS, 20, Charlotte Square, Edinburgh.

GREENHOUSE PAINTING AND GLAZING—"Vitrolite," superior to White Lead Paint, 18/6 per gallon, cans extra. "Plastine," the Imperishable Putty, 32/- per cwt., kegs extra; 7lb. tins, 4/-, post free; 14lb. tins, 5/6 each, carriage extra, tins free.—Full particulars from W. CARSON AND SONS, Grove Works, Battersea, S.W.11.

VOL. XC.—No. 2846. JUNE 19, 1926

TIDY TREES AND SHRUBS

A READER has written to the Service Department of THE GARDEN asking if clipping and grooming trees and shrubs is justified. Frankly, I have been unable to give him a satisfactory answer. I suppose it is largely a matter of taste; whether you prefer tidiness and neatness to natural growth. Of course, it can be carried to extremes, like everything else in gardens. One famous gardener invariably carries a pair of secateurs with him and snips here and snips there as he goes around his garden. The consequence is that his shrubs look wonderfully spruce and well kept, but rather too well barbered to my way of thinking. At the other extreme is the man who has a horror of cutting anything and who imagines that if he leaves a plant alone it will grow in exactly the same shape as it does in a wild state. His love of the natural is over-developed, since he forgets that a plant in cultivation may, of its own accord, grow in a very different fashion from its wild relative. This applies to every class of plant whether it be alpine, herbaceous or shrub.

It must be remembered that clipping and grooming differs entirely from pruning and thinning. The latter is often necessary in order to get the best results, in the same way as a rose or carnation is disbudded; the former is a method of making a plant conform to "civilised" gardening. Oddly enough, the grooming of a hedge is often slackly carried out; for here is a way of growing trees and shrubs in a purely artificial manner that must look artificial if it is to be successful. Nothing looks better than a well trimmed holly or yew hedge, and nothing looks more slovenly when neglected. Incidentally, training a hedge is not so easy as many people imagine, if it is to remain clothed to its base. One reason is that the top growth is spared too much so as to give immediate height. Hedges are better clothed if the shears are used regularly and rigorously and enlargement is allowed to be slow.

It is undoubtedly true that plants in gardens often vary from their wild form. They have more room in which to grow, better soil and better light, so the case of the man who leaves everything severely alone falls to the ground. Just one instance of this: there is a birch that comes from Korea called Betula Schmidtii, which Mr. Wilson describes as a tree up to 60ft. having a short stout trunk. Now every plant that I have seen in this country has this short trunk so accentuated that it grows in bush form branched to the ground. True, most of them are small as yet, but it is undoubtedly growing as a bush in this country. As few people have any use for bush birches in this country, owing to the large amount of room they take up, here is obviously a case for trimming the lower branches and definitely clipping it in order to give it some height. An example of the opposite can also be given. Most of the dwarf rhododendrons in the wilds form carpets often under 12ins. in height. Here, owing to cultivation and different climatic conditions, they often grow to bushes 3ft. in height and straggly at that, a totally unnatural condition. In this case I maintain that one is perfectly justified in clipping them and pinching them to a more reasonable size. I do this frequently with young plants, with the consequence that they break at the side instead of aping their tree relatives, with a bushier and happier growth.

What should happen is that each plant should be judged on its individual merits. If any rules could be given they might run something like this, though doubtless many will disagree with me:

1.—Evergreens can be trimmed with greater chance of neatness than deciduous without spoiling their natural appearance.

2.—The smaller and neater the leaf the more of a shape can be given to the tree or shrub.

3.—The larger the leaf the more must it be left to its own devices.

4.—No shrubs with whippy or arching branches can be trimmed.

5.—Before any trimming is attempted, find out if the flowers come on the new or the old wood—a very important consideration where any cutting is attempted.

6.—The same applies to trees and shrubs that produce their flowers at the tips of the branches.

It is certainly the case that an occasional trim up will save overcrowding and plants growing into each other, a most annoying thing when they are too big to transplant with safety. On the other hand, inconsiderate and careless barbering will not only remove many potential flowering shoots, but will also form plants in too symmetrical and shapely fashion. They will all look too much alike in shape, and uniformity is tiresome.

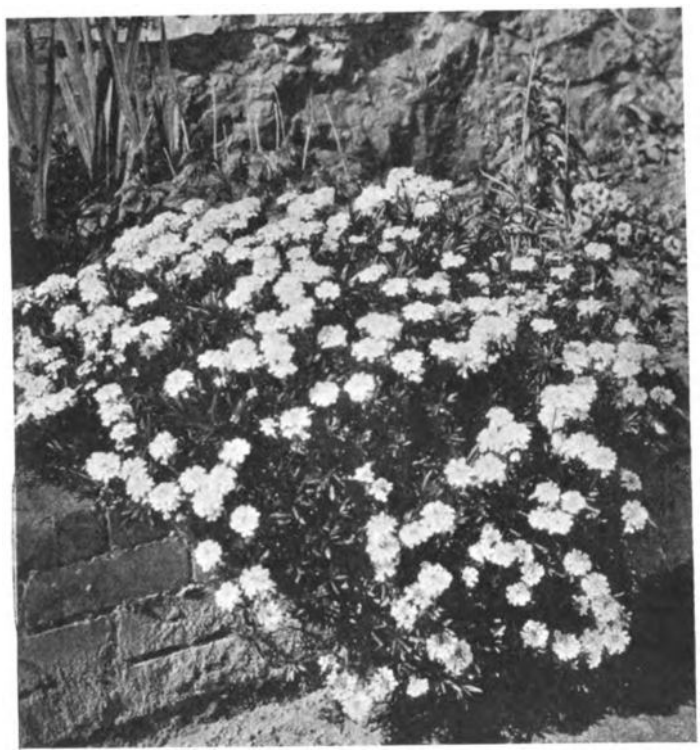
WORTHY PLANTS.—IV



IBERIS SEMPERVIRENS.

IT may seem to many a little strange that Iberis sempervirens should be raised to the exalted position in this column as a worthy plant. It is true, it may be considered common by the majority of enthusiastic gardeners; but is it so widely grown in the gardens of this country as it deserves? It can certainly be found scattered here and there in gardens; but in the smaller suburban gardens which are springing up round our large industrial areas it is absent, or nearly so. It is on this account, therefore, that we desire to draw attention to its merits. The iberids as a whole contain a number of fine garden plants, of which this species and corriæfolia are the two most outstanding. If given a situation which is dry, sunny and well drained, in light soil, it thrives for years without further trouble. Flowering commences, generally, in late spring and continues spasmodically throughout the summer, while the plants seed themselves copiously, and in addition, the stems, if broken off from the parent clump, root readily where conditions are suitable. There are many garden forms of this species, known under various names, such as Little Gem, Snow Queen and various others, and all form neat-growing clumps wreathed in a sheet of white blossom during the summer, which is made all the more dazzling when viewed in full sun. It soon makes a spreading and rather flattish bushy growth of a couple of yards or even more across and rarely more than 9ins. high. The foliage is of a rather dark-toned green, and is almost completely hidden from view when the heads of white flowers appear. It is a plant which should find a place in every garden, with its rich and sumptuous beauty. Still another point in its favour is the fact that it is most accommodating. It can be used for general effect as an attractive edging to a bedding scheme, or to a path or steps; while in the rock garden and rock wall it is unsurpassed for sprawling over vantage points such as corner rocks or sunny corners, which gain in beauty and appearance both in summer and winter.

WITHIN recent years many of the gardens in this country have been enriched to some considerable extent by representatives of the New Zealand flora, in alpines, trees and shrubs. Among the trees there is one genus which would seem to have drawn to it many enthusiasts, namely, the nothofagus, or the Southern Hemisphere Beech. Of the New Zealand representatives there are probably three, N. Menziesii, N. cliffortioides and N. fusca in cultivation in this country. The two former are fairly widely distributed and have attained a medium height, while the latter, as yet, is only beyond the nursery stage. All three, however, seem to take kindly to conditions in our gardens, although none is over hardy. It may be interesting, therefore, to those who are taking up the cultivation of these trees to hear of a recent publication which has reached our hands from Dr. L. Cockayne, who has, by the way, contributed articles on the New Zealand flora to THE GARDEN on several occasions. This work, a monograph on the New Zealand Beech Forests is written by Dr. Cockayne and was undertaken by him at the request of the New Zealand State Forest Service. So far, only Part I has been published, which deals primarily with the ecology of the forests and the classification of the Southern Beeches. Growers of nothofagus in this country will find plenty in the pages which is interesting and helpful. Much of the work, however, is principally concerned with forestry, since the beech is one of the chief timber trees of New Zealand and a thorough knowledge and understanding of its nature, habits and requirements are necessary before anything like accurate methods can be practised with an ultimate view to successful commercial exploitation.

AFTER a brief description of the beech forests, Dr. Cockayne puts forward a suggested classification of the species, together with descriptions, and a key which all gardeners who are interested in the genus, as well as foresters, will find of great assistance in identification. The species which he considers valid are the following five: N. Menziesii, N. fusca, N. truncata, N. Solandri and N. cliffortioides. Others which may previously have held specific rank, such as N. Blairii, he considers as hybrids, of which, apparently, there are many existing between the five species. The recognition of species is, on the whole, easy, as each has definite characteristics of which the most pronounced is the leaf character. A detailed account is given of each species, together with figures and illustrations and also descriptions of many hybrid forms. Some interesting observations are made on seedling and juvenile hybrids, when one interesting fact emerges: The short twigs which are so frequently put out from the naked trunks of many of our trees are really reversion shoots and indicate the leaf form of the young sapling when it was that height. This fact would seem to make the recognition of juvenile hybrids a matter of at least some certainty. Section III deals chiefly with the distribution in New Zealand of the various species and some consideration is given to the probable origin of the genus, which is principally of botanical interest. On the whole it is an interesting work and gardeners who are keen on these tall, symmetrical and handsome trees, which are now beginning to grace our gardens, would be well advised to give it a little study, as it will make the growing of the plants all the more interesting once something of their history is known.

THE Royal Horticultural Society intends to carry out a trial of freesias in its gardens at Wisley during the coming season, and it is desired that all those who are interested raisers should send corms to the Director. Five corms of each variety should be sent in order to reach the Director, R.H.S. Gardens, Wisley, Ripley, Surrey, on or before July 15th, 1926. The necessary entry forms can be obtained on application to him at Wisley.

AMONG THE ARTICLES IN OUR NEXT ISSUE WILL BE:

THE VALUE OF FOLIAGE—II, by John Hill.

A NOTE ON LUPINS.

Digitized by Google

A LITTLE PINK AND GREY GARDEN

How one can be made by the selection and combination of flowers whose colours harmonise.

THE paved path leading to the pink and grey garden has been given a little twist, like an elongated "S" to give it a certain air of antiquity. The silver thyme edging encroaches on the stones, and close to it a border of small pink daisies is planted, the kind called "Dresden China," a name so descriptive of their delicate charm. Two almond trees guard the entrance to the garden, and each spring these are covered with a wealth of pink blossom. A little grey gate leads into the garden through a bower of clematis with pale pink flowers (C. montana rubens).

Running through the centre of the garden there is a long pergola of pink climbing roses and ramblers, such as the American Pillar rose and Dorothy Perkins. Beneath, edging the beds on either hand, is a ribbon of pink thrift, with its fine tussocks of grey-green leaves. Behind this the real old-fashioned pink displays its silver foliage throughout the year and in due course its pretty pink flowers add fragrance to the walk.

Behind the low edging plants the pink flowers are arranged in bold masses with every here and there a plant of more imposing dimensions to break up the even appearance of the beds.

A few tulip bulbs are introduced among the other plants, such varieties as Cottage Maid for early flowering and the old favourite Clara Butt among the tall May-flowering Darwins. A few pink hyacinths might also be planted at intervals, but they are rather stiff for an informal little garden like this.

Here are pink stocks with pleasant grey foliage, and snapdragons of the palest pink intermingled with those of darker rose. Then there are clarkias set off by the grey foliage of Veronica incana, a sprinkling of Shirley poppies, and sweet williams filling some of the smaller spaces towards the front. Godetias of every shade of pink add their colour to the middle of the borders, also mallows and their cousins, the lavateras, and cosmeas, which are rapidly becoming great favourites among gardeners. Great clumps of pink border carnations

ARTEMISIAS AND SNAPDRAGONS MAKE AN EFFECTIVE COMBINATION.

A PLEASANT ASSOCIATION OF NEPETA AND ANTIRRHINUMS.

with their grey leaves to set the flowers off to the best advantage add their perfume to the air. Pentstemons of pale coral pink and those of rather darker shades are mixed with French lavender to form a contrast. Later on the lovely verbenas and the stiff, artificial looking zinnias are to be found in the beds. Rather taller the lovely long-spurred columbines of every combination of pink with other delicate colours rise from their beautiful grey-green leaves. Farther back the pink lupins are planted alternately with lavender which, however, is frequently renewed so as to prevent it becoming too woody and straggly. Then there are the annual larkspurs, both the single ones and the double stock-flowered kind. This latter has a very fine rose colour. The perennial phloxes take their place rather far back and form great masses of different shades of pink. Lilium speciosum rising from a carpet of catmint (Nepeta Mussini), opens its graceful bells, which show off well against the grey foliage of the catmint and blend with the mauve flowers of this little plant. Pink Canterbury bells planted near the lupins are ready to take their place when the lupins are over. For late summer and autumn we have the chrysanthemums, Japanese anemones and gladioli, such as the Prince of Wales or Maiden's Blush for a primulinus variety. Earlier, the small pink gladiolus with the very becoming name of Blushing Bride has flowered and passed. Right at the back of the beds the stately pink hollyhocks are to be found, both the double and the single kinds.

Among the plants of more imposing dimensions placed here and there in the borders are the newer pink peonies, with their great flowers nodding in the sun, a great improvement on the old purplish-red peony of years gone by, which has now been banished from the gardens of connoisseurs. In the early spring there is a plant or two of the bleeding heart (Dielytra spectabilis), an old cottage favourite, which has on this account acquired many a quaint name, often quite local in character. It is known as Our Lady's Necklace or Locket, Dutchman's Breeches, and in Devon it is sometimes called the Pocket Lily. A few old-fashioned pink cabbage roses, with their fragrance, a moss rose or two and a bush of sweet

Digitized by Google

briar, add an old world charm to the little pink garden. In a moist corner of the garden the pink spiræa unfurls its plumes; we must no longer call this spiræa, however, it is to be known as astilbe in future. Close by there is a pink broom, the grey green of its feathery leaves looks well all the year through, but when the pink flowers are there it is entrancing.

Dotted about the borders are little circles of sweet peas, each one different. Four of the best are Elegance, Picture, Annie Ireland and Countess Spencer.

At the end of the little pink and grey garden there is a low grey stone wall, over which all manner of small plants are allowed to grow, the pink flowers of one mingling with the grey foliage of another. Behind these smaller plants a row of dwarf polyantha roses bounds the garden.

Of the smaller plants let us see what is here. Pink sun roses, rock roses with grey leaves and pale pink flowers, soapwort (Saponaria ocymoides), a pink waterfall, next to which the grey-leaved Cerastium tomentosum is planted.

Then there are several members of the pink family, a beautiful little geranium (G. Traversii), with pink flowers and silver leaves; it hails from New Zealand. Oxalis rosea, which only opens its flowers if the sun shines. A dwarf evening primrose (Œnothera rosea), with large pink flowers and the pink heucheras, with which are planted the mountain cudweed (Antennaria dioica), it has pink flowers and lovely woolly leaves like those of the eidelweiss. Lastly, a few of the better pink mossy saxifrages are tucked in at the edge of the stones.

If the pink and grey garden were only a little bigger we might have hedged it around with flowering shrubs and trees, such as rhododendrons, weigelas, flowering currants, may and peach trees. What a number there are if space permitted to mention them all.

EDWARD CAHEN.

THE VALUE OF FOLIAGE—I

THAT the flowers in a garden are of great importance cannot be denied; but what of foliage—is not this of rather greater importance, serving as it does as foil or background to very many of the flowers? Further, foliage is at certain seasons almost our only source of beauty. In the general planting schemes of to-day every attention is paid to the arrangement of colour in flowers; but how often is the same degree of care applied in regard to foliage?

For the purpose of my articles I have divided certain trees and shrubs into definite groups; but as all, to my mind, claim equal attention, it becomes difficult to know where to start; but to many, variegation springs to mind. It certainly plays an important part in foliage schemes, and here again I will divide variegation into evergreen and deciduous sub-sections. Taking evergreens, ilex, I think, should come first. This family embraces some of the hardiest and most attractive evergreens we have; in fact, the large number of golden and silver varieties makes it more than difficult to select, say, only half a dozen varieties. One of the sturdiest and most brilliantly coloured is Ilex Aquifolium Golden King. This is closely followed by a rather finer-leaved variety, I. A. mediopicta aurea, known in nurseries as Golden Milkmaid. A holly rather out of the ordinary is I. A. ferox aurea, or the "Golden Hedgehog Holly," its foliage being more or less covered with spines. A good and first-class ilex of silvery hue is the beautiful Silver Queen, I. A. argentea regina. There are several weeping forms, and good trees of these are one of the greatest ornaments to a garden, especially when laden with masses of brilliant berries. I consider the best variegated weeping forms of Ilex Aquifolium to be Perry's Weeping, I. A. argentea marginata pendula, and the Golden Weeping Holly, I. A. aurea pendula. I will not mention more ilexes in this sub-section, but I may say that a host of beautiful varieties are easily obtainable.

Another very hardy subject is Taxus. Here again there are several outstanding varieties with elegant, but neat, golden and silver foliage, and, like the ilex, they adapt themselves to almost any position, graceful specimens for the lawn, even for hedges—in fact, the uses to which they can be put are of the widest scope. Taxus baccata contains the best varieties: they are the "Irish yew." T. b. fastigiata aurea and T. b. fastigiata argentea; T. b. elegantissima and T. b. alba variegata, the best golden and silver forms of the English yew. All the above are particularly bright and attractive.

For those who can grow peat-loving subjects there are two plants, both extremely beautiful but seldom seen growing to perfection; nevertheless, both, in good soil, are excellent growers. They are the variegated forms of Andromeda japonica and Rhododendron ponticum. Where there is room for many beautiful things the ligustrums should not be overlooked, as there are a few very brightly variegated, not least among them being our old friend, L. ovalifolium aureum; this, when kept nicely trimmed, makes a splendid pyramid of several feet in height. Other good forms are L. lucidum tricolor, L. l. aureo-variegatum and L. sinense foliis aureis variegatis. A beautiful and most useful little subject for groundwork for edgings or to beds or shrubberies is Hypericum Moserianum tricolor. Another of dwarf growth—*i.e.*, up to 3ft. or 4ft.—is Skimmia japonica variegata.

THE BEAUTIFUL FOLIAGE OF ILEX AQUIFOLIUM MEDIO-PICTA AUREA, THE "GOLDEN MILKMAID."

There is just one aucuba I must mention, and I consider it quite the best of a beautiful group It is A. crotonensis. It has magnificent foliage most brilliantly variegated and is well worth a place in the cold conservatory.

I will conclude my evergreens by mentioning just a few of the brightest, easiest grown and most easily obtainable conifers, as they in themselves form a very important colour group. Some of the cheaper forms—which, by the way, are quite good things—make excellent hedges or windbreaks. Taxus I have already recommended; but first in importance comes the cupressus, and of the cupressus, Lawson's Cypress. This species contains a wide range of beautiful and graceful growing trees. All are quite hardy and will grow in any good garden

Digitized by Google

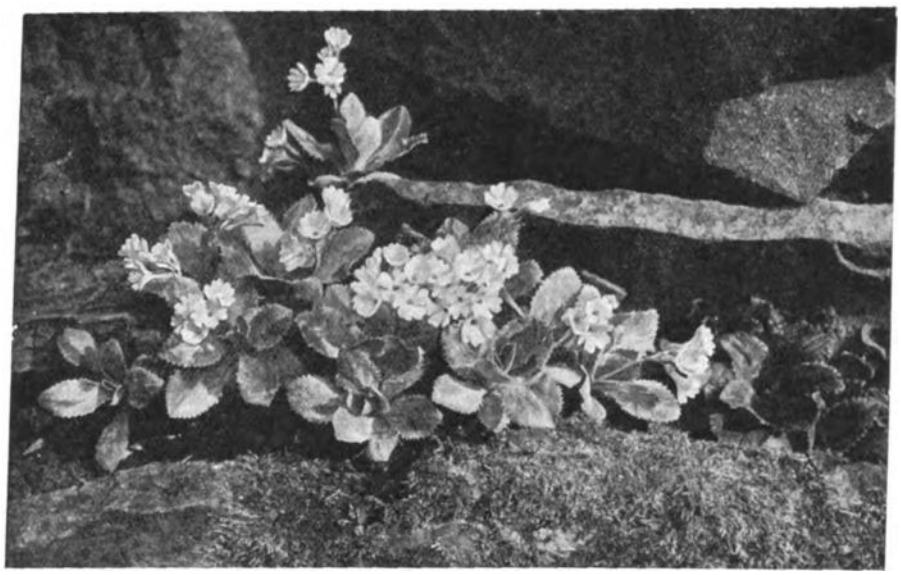
soil, but the golden forms are not too happy on chalky loams. I consider the finest variegated forms of Cupressus Lawsoniana to be C. L. Westermannii, gracilis aurea, alba-variegata, aurea-variegata and lutea; two other good golden varieties are Stewartii and Hillieri, both of which also belong to Lawson's group. Cupressus obtusa (retinospora of gardens) gives us some most brilliant things, as C. o. gracilis aurea, C. o. aurea and C. o. tetragona aurea. Cupressus pisifera also adds its quota in giving us C. p. filifera aurea, a beautiful subject for a specimen tree, with long golden thong-like shoots which, in the young stages, are quite pendulous, and C. p. plumosa aurea.

There are many golden and silver forms among abies, junipers, etc., many of which are of exceptional beauty and, moreover, quite easy to grow, and when grown in conjunction with other evergreens and deciduous subjects cannot fail to enhance the beauty of the shrubbery. JOHN HILL.

SOME PRIMULAS OF THE WESTERN ALPS

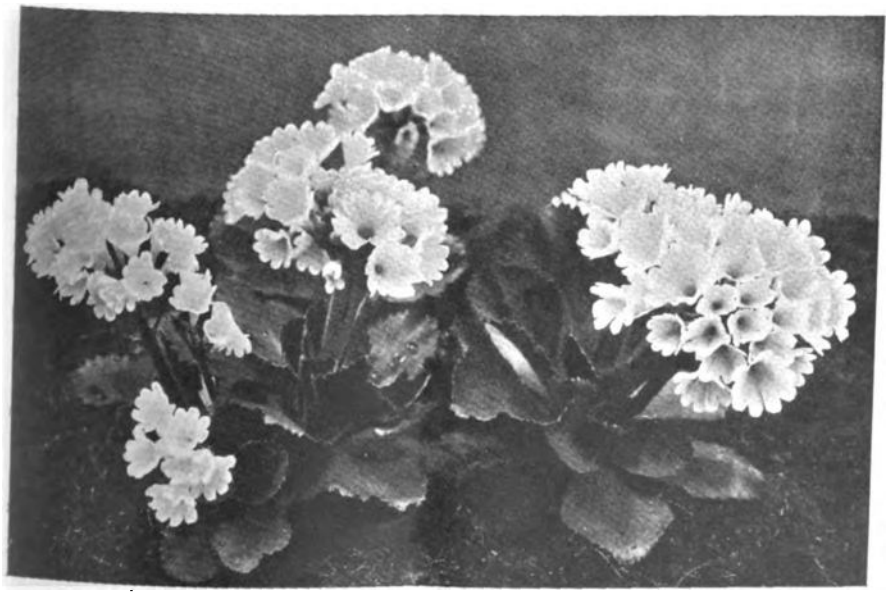
THERE is a confusion about Primula viscosa because two very different kinds of primulas bear that name. The Index Kewensis gives the viscosa of Allionii as correct, while in horticulture we call it latifolia or graveolens. In gardens the P. hirsuta of Allionii is called viscosa. Both plants are quite different from each other. The first one, P. viscosa (All.) has long glutinous, yellowish green leaves. The stem of the plant is thick and sometimes 8ins. to 10ins. long; the flowers are narrow and trumpet shaped, of a vinous violet lilac. It belongs to the central and western Alps and to the Pyrenees, always growing in the northern fissures or at the base of the granitic rocks in good deep leaf-mould.

P. hirsuta (All.) is a variable and polymorphic plant growing only on north faces or shady granitic walls of the Alps and the Pyrenees. It is one of the first to flower in the spring and, here at least, at Floraire, we have it just after P. marginata in early March. In catalogues this primula is known by the name of viscosa. This must be rectified if we are to have a correct nomenclature in our gardens. It is a dwarf plant, not exceeding 2ins. to 4ins., with broad, dentate, short and viscid leaves. The flowers vary from the brightest carmine to pure white. In some parts of the Alps, where the granitic rocks are adjoining lime or slate, the plant crosses easily with P. auricula, which is the calcareous primula *par excellence*. And there, it is possible to find in half an hour many of the forms which have been published under different names by some botanists.



ONE OF THE MARVELS OF EARLY SPRING, P. MARGINATA AS A CREVICE PLANT.

P. marginata, one of the marvels of early spring, adorns the cliffs in the Maritime Alps and in the western Alps as far as Mont Genèvre. It is the first to bloom in our gardens and from the month of February till end of March, or even April, it produces its pleasant lavender lilac flowers, slightly powdered with white. They form a large head on a stem of 3ins. to 10ins. long and the leaves are themselves a delicate feature, being thick and grey, very elegantly toothed and framed with a silver or golden meal. The whole is borne on a woody trunk, often very long (I have seen in the upper part of the Gorges du Cians, some measuring more than 1ft.), which gives the plant an aspect of a little shrub. Hence the name of "Primevère en arbre" it bears in France. The plant is one of the easiest to grow and seeds abundantly here. It only wants a fissure in the rockery or in a shady wall. It is variable both in colour of flower and in shape of leaf.



P. HIRSUTA WHICH FAVOURS SHADY GRANITE WALLS.

P. pedemontana is another beauty of the granitic rocks of the western alps, which is not common. It belongs to the Cottian and Grayan Alps, from the Col du Mont-Genèvre to the Val d'Aosta, including the Cenis. It is distinct from the viscosa group by its dark green and reddish, oval pointed shining leaves, surrounded with brown hairs; the flowers are of a rich carmine pink, with a clear white eye, borne on a scape of 3ins. to 5ins., thick and brownish. It flowers in April-May and wants a shady wall or the north-east side of a rockery.

P. cottia is the eastern form of P. villosa, a plant peculiar to the Austrian Alps. This is covered with a darker fur and has deep pink flowers. The P. cottia, from the Cottian alps at the north-east side of the Monte-Viso, differs from villosa by its shorter and smaller leaves, its shorter stem and larger flowers. The plant always grows on shady granitic rocks or walls. I once found a pure white form which I have lost. It is one of the

Digitized by Google

best of the hirsuta group and one of the earliest to bloom.

P. Allionii, from the high calcareous walls of the Roya Valley, is one of the gems of the alpine flora. I cannot describe the sight of the cliffs between San Dalmazzo and Fontan in the months of February-March when they are made brilliant by the pink carpet of these stemless primroses. They form dense cushions of small, round and greyish leaves which are often quite covered and veiled by the flowers. The plant is confined to the upper Roya Valley, but is very abundant on the highest, inaccessible cliffs.

It is easy to cultivate in our limestone at Floraire and grows equally well in granite. It only requires a half shady situation and a perpendicular position.

HENRY CORREVON.

GUIDANCE FOR EXHIBITORS

An article for the amateur who intends exhibiting at forthcoming summer shows.

A VERY ambitious title has been selected for a comparatively small set of notes, which probably will fail to live up to their heading, yet prove of some use to the would-be exhibitor.

Firstly, let me explain that it would be a sheer impossibility to deal with the whole ins and outs of the subject other than in a comprehensive volume.

These notes will mainly deal with vegetable showing, a form of competition in which the amateur has been taking increasing interest during the past ten to twenty years, so that, now, the classes which cater for this side of horticulture at shows rank among the most important.

When plants are growing away merrily, then comes the need for the most watchful care, for weeds prove harmful unless kept well under control; insect and similar pests, unless tackled at the onset and ruthlessly fought and destroyed, will soon work havoc among the specimens; and, above all, the soil requires to be kept constantly stirred with the Dutch hoe around the growing plants, so that the surface is well broken and aerated, and thus maintained in fine tilth and of moisture-retaining capacity. Mention of moisture brings one to another prime essential, water, a necessity to plants that is too frequently wrongly applied. A daily sprinkling may easily do more harm than good, and though it is beneficial to some plants at the end of a hot, dry day, yet, if this is the only system of application, one may well expect to see one's produce not making the progress desired, for it must be remembered that it is deep at the roots where plants require their main supply of liquid, to which depth the sprinkles will not reach, and, therefore, a thorough drenching at reasonable intervals will do the good that the light applications fail to render. Mulching in periods of drought is an effective aid in this water feeding, and in conjunction with watering it must be remembered that a feed with liquid manure water is of great benefit to many subjects for attaining good show specimens and table produce, and the judicious use of artificial fertilisers of reliable character, will also help on the good work, and repay the careful cultivator in the long run.

Having arrived at the point when, by unspared labour and watchful care, the produce has been attained that will do its grower credit on the show table, there yet remains much to carry out to make the best success of the efforts. It does not do nowadays just to dig up one's produce and dump it in the exhibition tent, as was too frequently the case not so many years ago, for now the competitions are too keenly contested. The skilled grower raises his product carefully and prepares it thoroughly, so that his items are not only excellent products, tastefully staged, but also items of interest and beauty in the show tent. When the specimens are got together for the selected day, then the primest and best balanced set to form a dish is chosen. Root vegetables are carefully washed free from dirt, useless roots carefully trimmed off, tops likewise attended to, and damaged leaves removed. The same care is exercised with regard to stem and leaf products, so that all the items forming a dish are as alike as the proverbial "peas in a pod."

All classes of exhibits should be as fresh as ever it is possible when staging them, and carefully matched specimens selected, remembering that it is the medium sized specimens that catch the judges' good opinion rather than the undersized, or the over-large ones. Material with "bloom" as its natural attribute should have this carefully preserved, and as examples we would recall the culinary pea, the grape, and the apple, for this is one of the points that counts with the judges. Flowers should be as long-stalked as possible, and everything free from blemish and undamaged. This latter is a factor that should be borne in mind where it is necessary to pack exhibits for conveyance to the show tent, for many a good exhibit has been spoiled by careless packing and handling.

Now a few special hints on the actual staging, especially to the novice. The old legal phrase "Time is the essence of the contract," especially applies to this operation, and the longer you can allow yourself for the work, the better, for hurried staging is often the cause of an exhibitor's failure. He perhaps, through this fault, puts up too few specimens in his dishes, or drops a prime specimen of flower, fruit or vegetable, damages it, and has not another to replace it, and so his exhibit is at a discount from the beginning of the show. Time is especially necessary when setting up a group, for when it is done and a survey of it is taken, the competitor perchance realises that it would be more effective to change the position of some of the dishes, with marked effect, and lack of time does not permit of carrying this out. Talking of groups brings up another point of showcraft, for an experienced hand will always have a reserve dish or two, for substitution purposes, should his first choice appear unsuitable when staged, or should he find himself hopelessly outclassed with any particular item by a fellow competitor.

One very important point to remember is to study most carefully the schedule under which one is showing, to get the exact meaning of all the rules governing the show, and to make sure that one has exactly what is called for, especially with regard to the number of specimens to be shown. In connection with this, emphasis should be laid upon the very familiar advice in schedules to the effect that "All exhibits should be carefully labelled" and the explanation that this will be called into play should competition be very close.

These notes may well prove helpful to the tyro, and all that need now be added is a final caution, that from the start of the ground preparation right up to the moment when the exhibitor turns his back on his exhibit when the clearing bell rings for him to leave the tent for the judges to set about their task, care and watchfulness are really the factors that form the royal road to success. Do not forget also that some have to be disappointed in stern competition, and if reverses do befall, let them be the incentive for renewed and greater efforts, until success is attained. E. BECKETT.

SERVICE FOR READERS

Though so many subjects are dealt with in each issue of THE GARDEN, it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, whether advice is sought as to—

RESTOCKING A GARDEN, COLOUR SCHEMES FOR GARDENS, THE BEST PLANTS FOR CERTAIN SITUATIONS, WHERE TO OBTAIN NEW AND RARE PLANTS, INSECT PESTS, NAMING OF PLANTS, AND THE HUNDRED AND ONE OTHER DETAILS RELATING TO THE GARDEN—

there is always information available from a staff of expert contributors and consultants; *and there is no charge for this.* It is one of the additional means of Service which THE GARDEN is glad to render to its readers.

Also, there is the further convenience which the Service Department affords of supplying readers with data about anything that is advertised in the pages of the paper. Thus, on receipt of an enquiry, particulars will be sent of, say, half a dozen things about which the reader seeks information. The only stipulation is that a stamped addressed envelope shall be sent with the enquiry.

All communications should be addressed to the Service Department, THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C.2.

NOTES ON DAFFODILS

THE daffodil season of 1926 has been the earliest and one of the very best in my experience, and the show held in the Royal Horticultural Society's Hall at Vincent Square, Westminster, on April 13th and 14th was a very fine one indeed, though it was evident that some of the flowers were getting slightly past their best.

Never before have I seen the hall occupied by exhibits of daffodils only, as was the case on this occasion. There must have been an immense number of blooms shown, as the display was most imposing. At the same time, there was plenty of floor space left so that visitors were able to see everything comfortably.

The largest and grandest trade groups were probably those put up by Mr. J. L. Richardson of Waterford; the Donard Nursery Company, Newcastle, County Down; Messrs. J. R. Pearson and Sons of Nottingham; and Messrs. Barr and Sons; while Messrs. R. H. Bath, The Welsh Bulb Fields, Mr. J. W. Barr, Messrs. Cartwright and Goodwin and myself contributed exhibits of varying importance; and Messrs. Seymour Cobbley, Limited, put up a striking exhibit of large masses of several varieties in market bunches.

The very large exhibits, staged, as they were, in the form of high, steep banks, when viewed more or less endwise presented an effect of almost bewildering beauty; the graceful pose of the flowers on their stems and the beautiful lines of their profiles were more apparent than when looked at from the front; while all the wonderfully exquisite and varied tints of yellow, varying from deep, pure and intense golds to softest primrose, vivid lemons, clear and cool lemons; white, pure and silvery, with entrancing touches of green, ivory, warm cream, even buff tints, and here and there a suggestion of peachy pink, with many points of vivid illumination provided by the orange and almost scarlet and crimson crowns of many incomparabilis and Barrii varieties, all displayed with that living and youthful freshness peculiar to the daffodil, made a most charming harmony of spring loveliness.

It is difficult to select flowers for special comment from exhibits so numerous and extensive, but the following are a few that seemed to stand out. In Mr. J. L. Richardson's group I noted Master Robert, a particularly fine large golden trumpet of much substance and good texture with a handsomely recurved brim to the trumpet; it is evidently a plant of immense vigour, as the stems were very tall and strong, and some foliage shown was literally as large as that of flag irises. Eskimo, also shown in this group, is a very shapely white trumpet of much substance and outstanding purity. Mytilene, which was also shown by a number of other exhibitors, came in for universal admiration; it was a large Leedsii of distinct and charming form and very high quality, having broad and smooth rounded pure white perianth and shallow saucer-shaped pale primrose crown of great substance, the stems are tall and strong, and it makes an ideal show flower as well as a superb garden plant. Silver Salver stood out as one of the most attractive things in this group; a small crowned Leedsii of the utmost refinement, pure snow white throughout both perianth and the flat crown, with just a touch of cool green in the centre of the eye.

The Welsh Bulb Fields, Limited, showed several flowers of charming and novel colouring, some of these were under numbers. B.98 looked as though it might be half-way between a Leedsii and a trumpet, a lemonade coloured flower with a paler halo at the base of the perianth; while B 112 suggested a triandrus Leedsii hybrid in form, but its vivid clear lemon colour left one guessing as to the parentage. Twinkle is a small Barrii with curious buff-coloured perianth and red eye; and Marvel is a big incomparabilis with starry ivory perianth and spreading crimson crown.

Mr. J. W. Barr's group contained examples of several charming and interesting species; among these the dainty and slender small golden single sweet Jonquil, which, though by no means rare, is seldom seen nowadays; and the much more uncommon and very delightful citron and ivory Tazetta Glandore. He also showed Milk and Honey, a very attractive white and pale lemon double; and King's Pirate, a very handsome Barrii with white perianth and a crimson rim to its crown.

Messrs. R. H. Bath, Limited, showed fine flowers of the beautiful new white trumpet Gaza, a flower with very broad, smooth, shovel-shaped segments, and a slender, not over-long trumpet; and Golden Goblet, a new Jonquil Ajax hybrid of which Mr. Leak has the highest opinion. He tells me it is extraordinarily robust and free blooming, and lasts an almost incredible time, which one can understand from its exceptional substance. It is practically of Ajax form, with beautifully flanged crown, intense self-golden colour, and smooth solid texture, while the flowers are borne on splendid tall strong stems. One of the most beautiful flowers on this stand was Naesam, a Leedsii of great refinement and lovely quality having broad beautifully clean-cut, sharp-pointed, pure white segments and well balanced faint lemon crown.

THE PINK-CROWNED LEEDSII MRS. R. O. BACKHOUSE

The Donard Nursery Company had a wonderful exhibit of superbly grown flowers; among these, Spanish Flag, an incomparabilis variety with white perianth and a very striking wide, almost flat, orange and gold crown, was a centre of interest to market growers. Vintage, also in this group, is a small white trumpet of exquisite texture and quality; while there were several bunches of an altogether lovely little hybrid Leedsii appropriately named Fairy Snow.

Messrs. Pearson's magnificent group contained many notable flowers; probably that which first caught one's attention was a goodly bunch of the Leedsii Mrs. R. O. Backhouse, whose long crown is soft, almost salmon pink; another enormous Leedsii was named Gertie Millar; this had a very large, broad, white perianth and an immense crown almost too large and wide for good balance, attractively tinged with lemon at the edge. There were several bunches of Moonshine, a large white triandrus Ajax hybrid with three flowers on the stem; and a very fine poeticus with rounded snow white perianth and solid brilliant red eye was named Striking; while Carmel, a bicolor trumpet of highest quality and geometrical symmetry, was an ideal show flower.

In Messrs. Barr and Sons' imposing exhibit the pink-crowned Leedsii Mrs. R. O. Backhouse was again in evidence; there were also several blooms of the supremely beautiful Beersheba, which is undoubtedly the finest white trumpet yet seen. I also noted General Pershing, a beautiful rich dark golden Jonquil hybrid; while another neatly built, attractive Jonquil hybrid was named Aurelia.

GUY WILSON.

NOTES OF THE WEEK

AN ALPINE WALLFLOWER.

A USEFUL wallflower is the dwarf alpine species, Cheiranthus alpinus, which I always grow as an edging for bulbs and early summer bedding. The plants grow in compact shape to a height of 4ins. or 5ins. The buds look very pretty embedded in the heart of the leaves, then these open to a lemon yellow and form a fine bright edging to the border. Seed is freely set as a rule, but care must be taken or natural hybridisation takes place with other wallflowers near, and the result is a scraggy individual, not by any means so useful and attractive. The plants are perennial, but the best plan is to raise fresh stock from seed annually. The plants also do well in the rock garden.—H. A.

HARDY TAMARISKS.

HARDY species and varieties of the tamarisk are not too plentiful, but those that are "hardy" are much more hardy than is generally realised. Erroneously supposed to succeed only in a sandy soil along the sea coast, they are found to develop quite successfully and to give every satisfaction inland, and that, too, in all kinds of soil, light and heavy. They are, it must be admitted, best in a dry, porous root medium; but soil need scarcely be considered, nor need exposure give cause for worry. Fast growers, as a rule, they can be cut back in March or April—this being all the attention which they require.

Having been so emphatic in the statement of general usefulness, I confine my hardy tamarisks to three species. Commonest of these is T. gallica, a popular type with feathery foliage reminding one of the conifers. The flowers are white or pink, in waving plumes, and they are highly decorative. T. æstivalis is equally vigorous in growth; the flowers in this case, produced a month later than the former, are a distinct red and produced with great profusion. T. odessana is equally free as regards flowers, but these burst forth early in the summer; it is not so large as the others, and is, therefore, distinctly suited to the small garden. The flowers are a rosy pink and very pretty.—LANARKSHIRE.

THE SCARBOROUGH LILY.

FEW plants are more widely grown than the Scarborough lily (Vallota purpurea), and yet a great many people are not entirely successful with this beautiful flower. Frequently the production of blooms is far below that which ought to be the case, and young bulbs are slow to come to maturity. Everyone who wishes to succeed with the Scarborough lily should pay attention to a few special points. Let the soil be composed of good fibrous loam, leaf-mould and sand in equal parts. The bulbs should always be placed some inches below the level of the surface soil and, before filling in, it is well to surround them completely with sand. Press the mould firmly round the bulb, as this makes a strong root growth and has a tendency to force its way upwards. The best time for planting a fresh stock is in June or July, when the roots of the bulbs are most active and before the flower stems have been sent up. Vallotas dislike frequent removals, and the finest displays of blossoms are always from those bulbs which have been undisturbed for a long while. A top-dressing of fresh soil with occasional soakings of weak manure during the growing season will prove beneficial. In the winter the plants should be allowed to dry off to a considerable extent, and, at all times, the maximum amount of sunshine is essential for the free production of flowers. By careful attention the Scarborough lily may be induced to flower with much greater freedom than is often the case. The bulbs produce offsets freely, and these should be removed with a stick to avoid disturbing the main roots.

In mild districts the outdoor culture of the vallota is worth adopting. At the foot of a south wall the plant will really thrive better than when grown in pots under glass.—S. L. B.

THE POPULAR TAMARIX GALLICA WITH ITS SWEEPING FEATHERY FOLIAGE.

FLOWERING HAWTHORNS.

THE hawthorn, or may, has been at all times a feature of the English landscapes in early summer, and at a very early date in the history of horticulture varieties of enhanced beauty found a place in gardens and shrubberies. All kinds are slow in growth but they are worthy of a greater popularity than they at present have; nurseries, curiously enough, possess fairly good stocks, and standards or pyramids of the finest description can be had.

Few think of growing the ordinary white or pink singles, but the double white and the double red are, indeed, gorgeous things in May and June, when they deck themselves along every branch with profuse blossom. Not the least attractive feature of them all is the heavy fragrance, which can be sensed at quite a distance from the tree; too powerful for a room, it has a cloak of superstition around it, but no one denies its richness when "scenting the evening gale." Other hawthorns of great merit can be had. Crataegus coccinea plena Paul's Double Scarlet, is a beauty, with large foliage and highly ornamental fruits. C. Crus-galli, the Cock's Spur, has also large flowers and bright orange red fruits; as the name implies, it is formidably armed with thorns, and it makes a good hedge bush. Of others, we might mention here CC. Douglasii, with shiny leaves and purple red fruits; Carrieri, with glossy, deep green foliage, large rose-coloured flowers and scarlet fruits as large as cherries. The Glastonbury thorn is quite a rare shrub, grown on account of the legend; flowering early in May, it occasionally takes the notion to bloom much earlier hence its Latin name, præcox. Though some writers class many others, like CC. Pyracantha and Lalandei, under the generic name hawthorn, we, in this district, exclude them according to some unwritten law, and confine the term to those mentioned above; indeed, a few would keep the name entirely for C. Oxyacantha and its varieties. Without entering into discussion, I simply laud the merits of the sorts I have enumerated above. All will grow in any garden soil; even town atmosphere has no material ill effect on them; they are unrivalled during May for profusion of bloom and sweetness of perfume, and the slowness of their growth may often be a strong point in their favour.—CLYDESDALE.

SOME HARDY LADY'S SLIPPERS.

AMONG the hardy orchids that can be grown outdoors the true cypripediums or Lady's Slippers are doubtless the most attractive. In the central European flora we know of only one species, C. Calceolus, while in eastern Asia and North America there are quite a number of beautiful species. The showiest of the American ones is C. reginæ, better known in the gardens as C. spectabile,

Digitized by Google

THE QUEEN OF LADY'S SLIPPERS, C. REGINÆ.

of which our illustration presents a fine flowering group in a garden in Bavaria. It deserves both its names, being really the queen of all the species that are in cultivation at the present time. From the note of Mr. Gurney Wilson in last year's volume of THE GARDEN, I learnt that it has been discovered, too, on the borders of China and Tibet. This is, indeed, a very strange fact, of great geographical significance. I have met with it a few times during my stay in the United States, and I recognise that it grows under about the same natural conditions as C. Calceolus, in mixed deciduous woods in rather shady places, but not in really wet positions. When the plant has found the right place in the garden it ought to remain undisturbed for years. This is the case with all Lady's Slippers. Sometimes it is rather difficult to start them, but once established they last a long time and usually flower every year.

Of the other species belonging to the same natural group as C. reginæ, C. californicum is sometimes seen in European gardens. Its flowers are rather small, but appear from six to twelve at the same time in the axils of the upper leaves. The sepals and petals are yellowish green, and the lip is whitish, while in C. reginæ the whole flower is white or the lip more or less pinkish purple. Whether or not C. guttatum, which is widely spread from central Russia to Alaska and British Columbia, can still be seen somewhere in our gardens, I do not know. So far as I remember, I saw it before the war in the then famous nursery of Regel and Kesselring at Leningrad, and in the Botanic Garden at Jena, Germany, where the late curator had one of the best collections of hardy orchids.

At the same place I also saw C. cordigerum, which is shown in the accompanying picture. I am, however, not quite sure if this plant represents the true species from the western Himalayas. The flowers are greenish with a white lip. It belongs to the same group as C. Calceolus. There are several other species in our gardens that are closely related to it. Of them, C. pubescens, from eastern North America, is rather similar, but the flowers have a pale citrine labellum and somewhat more brownish sepals and petals. It is sometimes regarded as a form of C. parviflorum with smaller flowers of which the lip is of a brighter yellow and flattened from above to below, not laterally. Another well known species from north-western America, placed in the same group with C. Calceolus, is C. montanum. It has brownish purple flowers with a fine white labellum. The narrow petals are much twisted and hang down.

A still rather rare species is the Japanese C. speciosum, of which the flowers are almost white, but the lip is more or less tinged with rose. It is a very charming plant.

One of the most distinct species, rather unlike our true Lady's Slippers, is C. californicum, which I have seen in a Dutch nursery, but unfortunately without flowers. It has two large ascending leaves, from the centre of which the scape rises, bearing several rather small flowers, of which the spreading petals and sepals are quite alike and of a brownish colour, while the short labellum is greenish. The flowers are said to be fragrant. —CAMILLO SCHNEIDER.

GENTIANA VERNA.

IN a deeply interesting and valuable paper by Mr. Clarence Elliott, which appears in the latest issue of the "Journal" of the Royal Horticultural Society (Vol. LI, Part 1) that experienced cultivator speaks of "Some Alpines I Have Kept Alive," and in the course of his remarks discusses Gentiana verna, and justly emphasises the necessity of roots. And here it is, I think, that so many plants of G. verna, which have fairly good roots to begin with, eventually fail. In nature it appears to thrive best where it grows among other subjects, where it threads its roots among the other plants, and, while the roots may be partially above the ground, they are kept moist by the herbage among which the gentian grows. I know many who have struggled and struggled in vain to retain this lovely plant in their gardens. One day in visiting a beautiful garden, now, alas! a wilderness, through changing hands, I was struck with the health and floriferousness of a good clump of G. verna. On discussing it with the owners it was pointed out to me that the plants were "mulched" with fine gravel, which kept the roots cool. In common with a few friends, who had had unsatisfactory results, I adopted this method and found it most valuable. The fine gravel appeared to be more satisfactory than the ordinary "mulch" of soil, which is generally so beneficial to other alpines. On examination I found that a number of the roots, which were very near to the surface, and were sometimes exposed with unsatisfactory specimens, appeared to be delighting in the gravel just above the surface of the soil itself. This is not given as an adverse criticism of Mr. Elliott's views, but rather as confirming what he says regarding roots.—DUMFRIES.

THE RIGHT WAY TO CUT FLOWERS.

MANY garden flowers, if cut in the right way, will last much longer than is usually the case. Different blossoms, however, call for different treatment. Here are a few points which are worth bearing in mind.

Sweet peas, for instance, should always be cut in the early morning with the dew on them. They will then be found to last longer and keep their colour much better than if gathered after some hours' exposure to the hot sun. By far the best way with roses is to cut the buds in the evening. Select those which are in an advanced state and show signs of being likely to expand on the morrow. Such flowers as iris, peonies and practically all kinds of lily should be cut just when the buds have started to open. All these, if gathered when fully expanded, have a very short life in water. Pick gladioli in the later

CYPRIPEDIUM CORDIGERUM WITH GREENISH FLOWERS.

Digitized by Google

afternoon, choosing stalks on which only one or two flowers have opened. Make a slanting cut and use a sharp knife. In passing, it may be mentioned that clean cuts, free from ragged edges, should be made whenever flowers are being gathered. In the case of gladioli, it is a good plan to let the spikes remain out of water in the sun for ten minutes or so. This is known to florists as the "softening" process; afterwards they are likely to stand well in water.

Often, dahlias prove a disappointment as cut flowers. These will keep a long time if, after cutting, the stems are stripped bare at the bottom and these are then put in an inch or so of extremely hot water. Remove the flowers to a dark corner or closet, and let the water get quite cold. Then arrange in the vases as desired. Shirley poppies are usually classed as among those flowers which cannot be used for table decoration. This is not true if the flowers are treated in the proper way. Gather the poppies early in the morning, as soon as they are open. Then hold the ends of the stems in a gas or candle flame until they are quite charred. Now put in the vases and the blossoms will stand surprisingly well.

Flowers of special interest for the morning and evening meals are convolvuli and evening primroses. Go out early and cut buds of the morning glories which are just showing a little colour. Then arrange these in vases on the breakfast table, and they will open in a most interesting way before the eyes of the family. The same kind of plan may be followed in the late afternoon with the evening primroses. Here, again, it is easy to detect those buds which will open by the little strip of yellow that can be seen. These buds will expand as the dusk falls and provide a demonstration of the exact way in which a flower opens.

When heavy rain threatens it is often desirable to gather flowers before they are actually needed in order to save them from damage. In such cases place the blossoms in jars of water and stand in a cool dark place. If the flowers have to be kept rather long and the weather is hot, cover them with damp tissue paper, which will help to preserve them. Never sprinkle water over flowers, as this is very likely to make spots on the petals. Never pick flowers and then put them straight away into the vases, as in a sunny room many of them will wilt. It is always better to give them a spell in some cool, shady place. If sending flowers by post, allow an interval of some hours between cutting and packing. Flowers cut and put at once into a box will certainly arrive in a very bad condition. It is really a good plan to cut the flowers overnight and then despatch as early as possible in the morning.

One curious point which many flower lovers may have noticed is that certain blossoms do not seem to settle down well with other kinds. Without attempting to prove that flowers have positive likes and dislikes, it is an undoubted fact that, in some cases, they do affect one another. For instance, sweet peas and roses are always best kept separate, and it is a bad plan to put these in close proximity even for a few hours. Mignonette is another plant that has an unwholesome effect on any other flowers with which it may come in contact.

Generally speaking, sufficient care is not exercised when cutting flowers to avoid the removal of buds that will come on at a later date. Often, in the desire to get a long stalk a number of immature buds are taken away, and this kind of thing should be avoided as far as possible if a continuous display of bloom is desired.—S. LEONARD BASTIN.

A SELECTION OF VINCAS.

MUCH as I can sometimes admire its virtues as a ground cover for rough, sunless places, I have suffered so grievously from allowing Vinca major to take a mean advantage of my indiscretions that it must be excluded from this selection of periwinkles.

V. minor can be ruthless, too, but, confining the stronger growers, like the dark green, narrow leaved double blue, to woodland retreats, hospitality must always be accorded some of the many other cheerful little spring bloomers of this variable fraternity. The singles are, I think, the prettiest and in these my fancy leans to the pure white, the pale and dark blues with silvered or golden foliage and good forms of the type. The latter, however, varies very considerably even in its native haunts. One finds, for example, plants with well rounded flowers, the corolla lobes being blunt, while others have the latter so sharply pointed to one side and starred that they suggest a whirling fan. Blooms of this description on some plants gathered in Switzerland are a rich violet and 1¼ins. across. Another first rate periwinkle, not too vigorous, is V. minor Bowles' Variety. This has still larger blossoms than the last mentioned, with broad, blunt segments in a soft cat-mint purple, which is very delightful in subdued light. One estimable virtue possessed by all the lesser periwinkles is their long flowering season (February to July), and another is their willingness to thrive in almost any soil in sun or shade. But, like all others of their kind, they take time to become established.

V. difformis (acutiloba) is apparently a southern form of V. major. But even in its native habitat it is rarely so rampant as the latter and it is always a more refined plant. Further, being a little tender, it can be used almost anywhere without much fear of its spreading unduly. This periwinkle also differs from V. major in that it is a winter bloomer, coming into flower in November and continuing during mild weather until May. The flowers, borne on stately growths a foot or so in height, are rather smaller than those of the common periwinkle, the corolla lobes are sharply pointed and starred and the colour a very pale starch blue to pure white. In some of my plants growing in shade the blooms are a pure snowy white in autumn and winter, but those of spring are infused with the thin wash of blue. In large areas of V. difformis seen in flower last March in southern France, I found no variation from that delicate icy blue whiteness, but there are pale lilac and grey white forms common to other Mediterranean localities. If a little tender, V. difformis will stand 20 degrees of frost, but, being a winter bloomer, it is well to give it a place with some shelter, such as a partly overhanging tree. It will prosper in any light, cool soil.

V. herbacea has struck out a line for itself, it being a herbaceous species, dying back to the base in autumn. This is really a choice rock plant, delighting to weave a network of its long, slender trailers and narrow leaves over any fairly sunny slope and this it adorns with an abundance of pretty violet stars from spring well into summer. As the stems of V. herbacea root at the tips, like those of other vincas, increase is a simple matter.—A. T. JOHNSON.

VINCA DIFFORMIS IN A WOODLAND RETREAT.

AUTUMN TINTS IN MAY.

RHODODENDRON kamtschaticum, a native of north-east Asia, is, to lovers of the genus, a very interesting plant. In appearance it is dwarf and shrubby, about 6ins. to 8ins. high, and may be described as forming dense tufts from which it increases in size by underground suckers. Being deciduous and starting very early into leaf, it is at a disadvantage in having the young leaves and shoots badly cut back by late frosts. Except for this, it is very hardy, and stands the effects of a cold and rigorous climate.

The flowers are of a rosy crimson colour and, unlike the other species of rhododendron, this one produces its blooms on the current year's growths, which rise an inch or two above the dense pale green foliage. For its successful cultivation, a mixture of leaf-soil, peat and sand is necessary; but it is advisable to add some broken sandstone and sphagnum to keep the whole open and moist, thereby encouraging sucker growth. A damp situation with partial shade will also be in its favour, as, from observation, it grows much better in a wet season.

It has been cultivated in the Royal Botanic Garden, Edinburgh, for many years with success. Also, it may be of interest to note that, so early this year, the foliage has taken on a vivid red autumn tint, making the flowers difficult to locate among the dense coloured leaves. This is due, no doubt, to frost, and may prove a disadvantage to the plants later in the season. Nevertheless, a group at present (May 20th) of this hardy little shrub is very attractive and decorative among the rocks in the rock garden.—A. McC.

CORRESPONDENCE

DARWIN AND MAY-FLOWERING TULIPS.

SIR,—I look upon these with increasing admiration as each season comes round, and now consider them indispensable in a garden of any pretensions at all. For house and garden decoration at this time of year there are no other subjects comparable with them. But why will people with small gardens, who purchase a few dozen, persist in spreading them over the whole area. One here and two there, instead of grouping and producing a colour effect which is arresting and pleasing to everyone. The well known combination of Clara Butt over forget-me-nots, one never tires of seeing, there is something indescribably beautiful in the soft tone of pink over blue. By contrast a bed of Farncombe Sanders or Europe over an undergrowth of Munstead polyanthus is very effective. The dark and very noble King Harold lends itself particularly well to this kind of association.

In many small gardens, I know one has to be content with groups in mixed borders; in this case I have found a group of columbines on one side and delphiniums or lupins on the other, to be an excellent foil for the tulips, the foliage being fresh and green and just at the right stage for a setting for the glorious colours of the Darwins.

To those who, like myself, are limited for space, however, I would say, plant not fewer than twenty or twenty-five in a clump—if fifty, so much the better.

I have tried various kinds of foliage with tulips for home decoration. The well matured foliage of the columbine is quite pleasing, but I have found nothing so good as our old friend Solomon's seal. Used sparingly and cut in a fresh state with tulips just opening, the effect is most pleasing and flowers and foliage will last a fortnight with good treatment.

The lovely Baron de la Tonnaye cut at the opening stage, is particularly good indoors, and—but they are all beautiful. Make notes now for next year.—HENRY JENKINS.

GOOSEBERRY PESTS.

SIR,—In a recent issue of THE GARDEN you dealt, under the above heading, with several of the worst insects that infest that fruit; but there is one pest, if it can be so termed, that is far worse to deal with, and which is rapidly spreading in this district—this is American mildew. Perhaps some of your readers will be able to give their advice or their experience with the various sprays that are used to prevent or check this disease. From my own experience, I think there is practically no cure for it, and the best remedy is to burn the bush as soon as it is noticed; but I would very much like the experience of others and their advice on the following questions:

(1) After digging up and burning the present stock, how long before it should be planted in the same spot again?

(2) Is it possible to spread the disease with tools or one's clothing to other plantations, or does it spread like potato blight?

I have a large quantity, and am anxious to learn what is best to prevent it.—W. H., *Ottery St. Mary*.

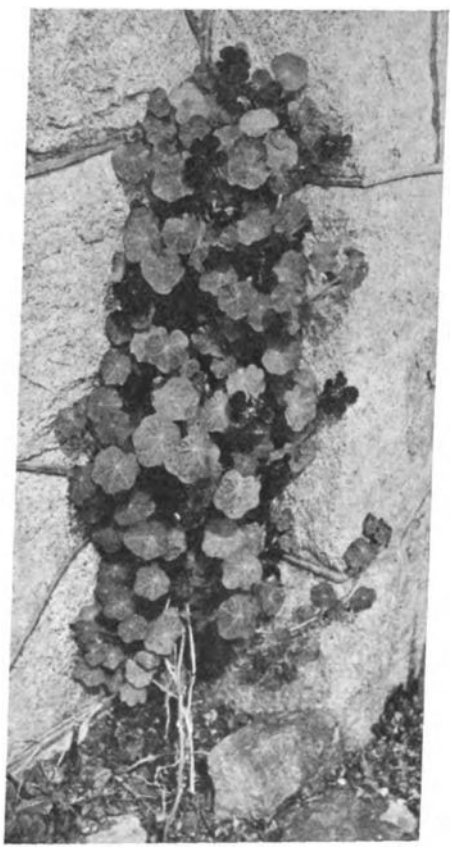
THE CULTIVATION OF CINERARIAS.

SIR,—Having regard to your interesting notes on the growing of cinerarias, in a recent issue, I thought it might possibly interest some of your amateur readers whose time and space are limited and who, perhaps, have difficulty in getting really good potting soil, to know that I have grown quite fine cineraria plants by simply pricking off the seedlings into boxes, placing them in a cold frame, when ready for the next move planting them out in an open space in the kitchen garden (allowing plenty of room for growth), lifting them before there is fear of frost, and potting them into the pots in which they are to flower, placing them in the cold frame prior to removal to the greenhouse.

A self-sown seedling taught me to try this plan, and I have thought the plants much better and less addicted to green fly. They are no further trouble once they are planted out, requiring no more attention or watering than other plants.—H. MEDLEY, *Scarborough*.

GARDENING IN VANCOUVER'S ISLAND.

SIR,—Should you have space in your valuable paper, perhaps the publication of these notes will give some idea to those of your readers who have not been there of the gardening conditions in the area about Victoria, Vancouver's Island. Last winter having been exceptionally mild, many flowers bloomed continuously out of doors, and many ordinarily tender plants survived outside and are now in a second flowering season.



A WELL-FLOWERED CLIMBING NASTURTIUM IN VANCOUVER'S ISLAND.

In my garden, Geum Heldreichi kept opening a few blooms through December and January. Then after a short rest it began again, and is now a mass of orange. Violas, pansies, marigolds, Geranium Robertianum, Gentiana acaulis and many others, including stray roses, brightened the dark winter months. Iris pumila and hybrids are now over, and most of the so-called "June iris" are now in full bloom (this is April 20th). Iris tenax is a mass of bloom, having started at the beginning of the month. There will be no iris flowers in June this year, as they will be all over before that.

Linum narbonnense and Romneya Coulteri have acted as evergreens. Any gladiolus corms left in the ground last autumn have come through and now have shoots from 6ins. to 12ins. high. Japanese wistaria, white and pink Clematis montana and several species of cytisus are in full bloom now; but I think the most wonderful thing of all, the first instance I know of here, has been the survival in the open ground, in an angle of a wall in my garden, of a plant of the climbing nasturtium, ordinarily due to perish at the first suspicion of autumn frost. This plant flowered last year, grew all winter, was in full bloom the first week in April, and has continued so up to the present. I am enclosing a photograph of the plant, which is about 3ft. high, with a head of foliage and bloom over 12ins. across. Near by there are a number of salpiglossis plants which, after flowering last autumn, are now throwing out numbers of strong flowering shoots.

Plants of the "marguerite" Chrysanthemum frutescens planted out last summer in a neighbour's garden have bloomed all winter, and in my own garden plants of Trachelium cœruleum have lived over and are now growing well, while in the next garden to mine several plants of Gazania splendens have grown all winter and will soon be in bloom.

In the rockery I have a plant of Ramondia serbica which has been in full flower for a week, with R. Nathalie beside it throwing up flower-stems. Such things as Phlox subulata, Iberis gibraltarica and sempervirens, Silenes Hookeri and glauca, Saponaria ocymoides, Æthionemas Warleyense and pulchellum, many aquilegias, Daphne Cneorum, the beautiful shrubby Pentstemons Menziesii and Scouleri, with the fine white form of the last and a host of other things, are in full glory, with Gentiana acaulis and G. verna about over and Cypripedium montanum just showing buds. One could write of many things more, but I fear I have already gone beyond my limit. We have a wonderful climate for gardening here, and the mildness of the past winter has permitted all outdoor plants to strengthen most wonderfully.—WALTER B. ANDERSON, *Victoria, B.C.*

CAPE BULBS IN THE OPEN.

SIR,—In response to your query in THE GARDEN of April 24th, as to the hardiness of these in the open, perhaps my small experiences with them may be of some use. We had 12 to 14 degrees of frost and snow and icy winds, yet freesias have been in bloom since the second week in April—as early as those under glass, but no heat. Some three years ago I scattered the small corms about, and they bloom every year. Hypoxis villosa, Crinums Powelli and capensis, and another Transvaal crinum, not yet flowered, have come through without harm, also tritonias. Gladiolus tristis is now in flower. GG. primulinus (in damp), Saundersi and dracocephalum do well in the open in the Wight. I should say that a "hot rocky bank," with leaf soil (or sand-bedded), would grow these bulbs admirably, especially if sheltered by shrubs from the early eastern sun. Lachenalias, some, are almost hardy here. Clianthus on the house wall in bloom second week of April and the first flowers of Rosa Hugonis also, and R. Banksia this week, and the flower panicle of Cordyline australis is showing its white buds.—C. M. B., *Isle of Wight*.

PLANT NOMENCLATURE.

SIR,—I am glad that Mr. Dalrymple likes my suggestion of "Pipes of Pan" as a suitable name for a new freesia, and in reply to his query as to the most suitable colour, I would suggest primrose as appropriate; but, indeed, I think the name might be given

Digitized by Google

to any variety of pale or delicate colour. As Mr. Dalrymple says, naming is undoubtedly a very difficult job, but at the same time it is interesting, and I often think it merits more care and attention than many raisers appear to give it. Some flowers, of course, lend themselves to attractive names more readily than others, and though I have no experience with freesias, I should think that they offer a very promising field for originality.—CECIL M. BAILEY.

SIR,—In discussing the above subject, I note that Mr. G. H. Dalrymple considers Narcissus Silver Salver to be aptly named. This is one of the Brodie of Brodie's seedlings, and he sent it to me under a number, asking me to give it a name. Its beautiful silvery white, almost flat crown suggested the name Silver Salver, but it is difficult to please everybody, and I remember the late Mr. Jacob complaining to me that it savoured too much of sherry and sandwiches! In any case, I have found that careful and thoughtful naming of a flower is well worth while; and it may but need not, be a matter of surprise to learn that a fitly named plant is a better commercial proposition than an ill-named one.—F. HERBERT CHAPMAN.

GARDEN TECHNIQUE

THE FLOWER GARDEN

SAXIFRAGA ELIZABETHÆ.

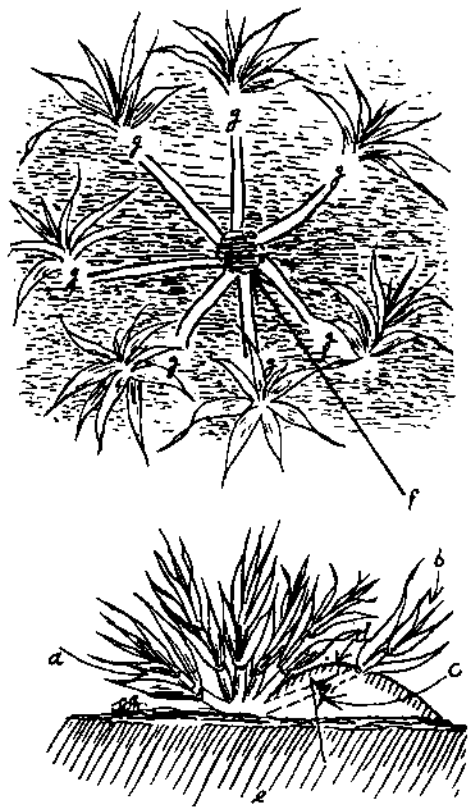
WE have now such a wealth of lovely Kabschia or cushion saxifrages that it seems an unthankful task to single out any one of them and to say that it should be grown wherever these charming flowers find a congenial home. Yet, without intending to decry any of the other dear charmers, one may, with advantage, say a word in favour of Saxifraga Elizabethæ, said to have been chosen to bear the name of Carmen Sylva of Rumania. It is one of the bonny hybrids now becoming so numerous in its class.

Its parents are S. Burseriana and S. sancta. From the former it has derived its free-flowering and from the latter its colour, a kind of sulphur yellow, but perhaps a little warmer in tone than that tint would suggest. The flowers are also larger than those of S. sancta, which in some places is exceedingly shy. It forms a cushion-like mass of deep green, spiny foliage, and, set on this in early spring are the numerous bright flowers. It is easy to cultivate, and the writer has grown it in poor, hard soil on an elevated part of the rock garden, as well as in better soil lower down, the one in sun and the other in partial shade. In both cases the plants were quite happy.

It can be increased by cuttings or careful division, but many succeed by simply tearing large plants in pieces and replanting them. As old plants occasionally become bare in the centre, the last method may be adopted with these. Plants in or just out of pots may be purchased and planted at any time. I prefer these to plants from the open ground, which may be planted after the flowering time in the course of summer or in autumn. —S. ARNOTT.

LAYERING BORDER CARNATIONS.

ALL plants that are to be layered in July should be prepared in good time. The preparation consists in the clearing away of all dead basal "grass" found on the side shoots now growing freely and which will be selected for layering, also, all foreign matter found under, or near to the side shoots. All necessary pegs required should be prepared, whether these are made of wire, wood or the stems of bracken fern where the latter is very plentiful. The compost, too, should be mixed so that everything will be at hand when the day comes for the actual layering to be done. Carnations will root readily in well rotted leaf-mould, but, if the soil used is naturally light, then be sparing with the leaf-mould. Builders' mortar rubble, if obtainable, may be used in preference to sand; but in every case it is beneficial if a small quantity of coarse sand is placed under, and on, the cut portion of the stem which is buried in the prepared compost. At *a*, a side shoot is shown before it is denuded of any basal leaves; *b* shows one properly prepared and pegged down as shown at *c*. There should be a 2in. covering of soil above the stem, shown at *d*. The pegs used ought to be long enough to penetrate into the border soil *e*, then they will hold and prevent the growing stem lifting the layered side shoot. At *f* the old plant is represented, with the side shoots, *g*, neatly layered all round it, though, of course, they will be close up to the parent plant. The surface of the border soil should be lightly forked up directly the



work of layering is finished, and care taken that the layers are not disturbed. Apply water directly the carnations are layered; use a fine rose on the can and keep the soil—the new compost—consistently moist until new roots are plentiful. Try to get the layering done as early as the conditions of the plants will admit; then it will be possible to plant out, or pot, early in the autumn—a great advantage.—G. G.

VIOLAS.

Notes on Varieties.

FOR a lengthy display of beautiful blooms one can hardly find a better class of plant than violas, or tufted pansies as they are sometimes called. One has only to grow a few plants to find how well they fill the finest beds or borders with brilliant colours, from the month of May onwards.

It is true that plants are in flower before the month stated, but in May the blooms are more numerous and certainly they are better coloured. From the first week of May onwards the following varieties have been blooming profusely:

George Woodgate, a beautiful Wedgwood blue; Maggie Mott, soft mauve, both young and old plants of this last-named variety growing in a long straight line near the box-wood edging are very effective. The old plants being somewhat bushy are better furnished with flowers, but the young eight months old plants have produced large individual blooms.

Bute Yellow is a splendid kind and gives a brightness of tone on the hardy plant borders. Young plants of Parson's White—not really a large-flowered kind—are also adorned with blooms. Marchioness is a creamy white variety of many years' standing. Shoots of this kind were dibbled into the ordinary garden soil on a sheltered south border at the end of August and left without any protection throughout the winter. The cuttings rooted splendidly and were fine healthy plants when set out a few weeks ago. Saughton Blue is a pretty viola, although the flowers are somewhat small. It appears to be grown under several names. For a royal purple, Dunattor Waters should suit most tastes; while Fred Williams produces large blooms of a royal blue tone.

Mrs. Manison has peculiarly shaded flowers of a very dark velvety crimson, with some petals streaked with white. This magnificent variety should flower well later. —DAVID ARMSTRONG.

THE GREENHOUSE

ZONAL PELARGONIUMS.

Their Preparation for Winter.

WILL the zonal pelargonium ever be regarded seriously in the light of a plant for blooming in a temperate greenhouse during the winter months by amateurs, or will they continue to look upon it solely as a somewhat old-fashioned plant for summer beauty indoors? It is curious that, while many take trouble in preparing other things to make the greenhouse gay in the dull season—as, for example, chrysanthemums, primulas, cyclamens—few amateur gardeners consider it necessary to ensure so commonplace a subject as the "geranium" any preparation at all, appearing to think that all one needs to do is to place them in a warm temperature as November approaches, notwithstanding the fact that they have given of their best in summer! When it is remembered that there are few plants so easy to grow, give so wide range of colour and, kept in a healthy condition, are seldom troubled with enemies, it seems strange that so few gardeners are enthusiastic about a feast of beauty which these pelargoniums will provide, if only they are grown on with that object.

It is within the realm of possibility that this note may meet the eyes of some who have zonals struck from cuttings, either last autumn or this spring, and, if this is so, I would suggest their setting apart a number of those plants with a view to special preparation. There is no time more favourable to commence the work than now, and, presuming the plants are in 60-sized pots, I recommend that they be removed into 6in. pots. If some of the zonals are extra vigorous, one may even use pots slightly larger, although for all practical purposes, 6in. pots are ample. The composition of the material in which the plants are to be grown is one which should be given special consideration. Nothing is better than good friable turf, which has stood a few months, leaf-mould (or spent hops will do equally as well), partly decayed cow manure, and sharp silver sand. Pots should

Digitized by Google

be clean, and firmness in the matter of potting is desirable. In this compost, zonals will quickly establish themselves, and until they do, it will help them if for a few weeks they can be quartered in a cold frame having a south aspect. It is in the nature of a zonal at this time of the year to be continually sending up flower buds, which must immediately be pinched off, and no exception to this rule ought to be permitted, however "fat" and promising such buds may be. Briefly, it is the holding up or conserving the energies of the plants from now until October that will ensure vigorous flower spikes at a time of the year when they are doubly precious.

One may continue to keep plants in frames with lights off, but it is preferable to follow the plan of dealing with chrysanthemums, and locate them on a bed of ashes out in the open, where sun and air may do their part towards ripening the wood. Zonals should not be allowed to want for water, and it will be beneficial to give them weak stimulants occasionally, when it is known the roots have reached the sides of the pots; until that time clear water only should be administered. Those who have been accustomed to grow plants in pots only under glass will be surprised what outdoor treatment in the manner described does for them, as by the middle of September, when it is time to bring them indoors, they will be found to be robust, and on introduction to warmth, buds soon appear. I use the word warmth advisedly, as, with a temperature of 50° Fahr. minimum, one can rest assured that the plants will bloom for many weeks; indeed, it is only a matter of arrangement to have zonals in bloom throughout the year; but, as we have said, they are never more appreciated than when their glowing petals open in November and onwards. While singles offer the grower a wide choice, he will be wise to include some of the semi-doubles also, of which that old and well tried variety, F. V. Raspail, is worthy of culture for winter. —W. LINDERS LEA.

TREATMENT OF SEEDLING PRIMULAS.

PRIMULAS, delightful flowers for furnishing our greenhouses during the winter and spring months, thrive best in a cool temperature and moist atmosphere. Position, during the summer months, is a very important factor in their management. If it is one that affords protection from the direct rays of the sun and, at the same time, admits plenty of light—preferably a northern light—it will be an ideal one. Detached frames may be placed with their lights facing due north; in such, the plants, placed on a thick bed of ashes,, will thrive if other matters are carefully attended to. Night air is good for these plants, so ample ventilation should be the rule, with the degree of moisture immediately around their roots always consistent. This means that watering should be carefully attended to, and clear water only used during the whole of the summer. The roots of the plants are fibrous and easily damaged, so in the potting compost do not include any strong manures. Fibrous loam and sweet leaf-soil in equal proportions, with a free sprinkling of old crushed lime rubble and a small proportion of well rotted manure, will form an ideal compost. Do not press down the soil too firmly. Seedlings, forming succession batches, should first be transplanted near the sides of pans or 6in. pots thoroughly drained. In this position they generally succeed well. Then the first potting, singly, into small pots should take place, and subsequent repottings until the plants are shifted to their flowering ones, which should be, for general purposes, 6ins. across.—HANTS.

TOMATO PLANTS UNDER GLASS.

THE sketch shows a tomato plant of the main batch as now growing under glass in amateurs' glass structures. Either where a little artificial heat was used to start the plants well or where the plants were grown on without any artificial heat but simply that obtained by husbanding the sun heat as much as possible consistent with the due admission of air.

Hundreds of amateur cultivators will possess batches of plants in the stage of growth shown, and from this stage onwards a great deal depends upon detail treatment if heavy crops of fruits are to be obtained. At *a*, *a*, a top-dressing of really good loam and rotted manure, mixed, will do a lot of good. The cultivator should examine the

soil and the condition of the roots. If there are numbers of the latter showing white on the surface, whether the plants are grown in pots or borders, apply a top-dressing in a lumpy, not fine condition. It does not matter if the new soil buries the lower part of the stem of the plant, as new roots will soon grow from it and permeate the soil. A second top-dressing would be beneficial, especially if food in a liquid form is difficult to obtain. At the stage when two trusses of fruit have formed and are swelling, shown at *b*, the first application of food should be given, whether in liquid form or as a dry dressing; and, of course, this feeding should be continued until the last truss of fruit is maturing. At the stage shown in the sketch tomato plants require very liberal supplies of clear water, and liquid food may be given at alternate waterings. When the fruits, shown at *c*, are well developed, the most forward ones at the bottom will be changing to the ripening stage, and very soon the plant will be relieved at the base, this enabling it to mature those higher up all the better. Stopping the plants is a very important point. In order that one may reap the heaviest crop the plants must not be allowed to grow to waste—to continue to bear fruits that will not ripen. Very late-raised plants should be stopped at the point *d*, while early-raised ones may be stopped at *e*; then every tomato retained, respectively, will ripen. The stopping at *e* may take place in July, and the one on late plants at *d* in August.—GEO. GARNER.

CARE OF FRUIT IN THE COLD HOUSE.

AS the climate in this country cannot always be relied upon to be quite favourable for fruit growing in the open-air, we find that many thousands of trees are grown under glass, in houses not artificially heated. The protection afforded by the glass is sufficient to ward off light spring frosts, and the husbanded heat ensures early-ripened fruits of peaches, nectarines, cherries, plums, and some choice sorts of apples and pears. But, at this season, there is always some risk to trees growing under glass. The management must be good. These cold structures should be carefully and consistently ventilated to prevent an undue growth of sub-lateral shoots, the spread of insect pests and to encourage the thorough ripening of the fruits and the shoots and buds that are to yield next year's crops. To concentrate the strength of each tree on this year's crop and the main wood, all sub-laterals must be removed while very small, or overcrowding would soon occur. All fruits should, at this time, be exposed to the light and sun as much as possible, Watering and feeding are two essentials. Be sure that the border soil is consistently moist; then pay attention to feeding, using artificials and liquid manure. Syringe freely to prevent red spider; fumigate to destroy aphides, and, for the latter purpose, have the foliage dry and the floor damp.—CHRISTCHURCH.

THE VEGETABLE GARDEN.

POTATO CROPS.

The Importance of Earthing.

POTATOES generally do well in new ground, that is, ground that has not been cropped by potatoes before or, at least, for many years. One reason for their succeeding so well is because such soils are thoroughly worked before the tubers are planted; it is, also, mellow soil. We should, at this stage, continue to stir up and break lumps of soil between the rows; it is commonly called hoeing potatoes and this is done, mainly, to kill young weeds. But, as stated above, all lumps should be broken up as well as weeds; potatoes like a fine soil to grow in. In a short time it will not be possible to hoe between the rows except in the centre on account of young tubers forming in the ridges. Then there is the earthing-up work to be done. It is rarely wise to neglect the timely earthing-up and it can never be neglected without detriment to the crop except, perhaps, in really light, sandy soils. The runners on which the young tubers grow permeate the soil where there is most moisture and that will be, before earthing up is done, about 6ins. away from the stems. If the work is unduly delayed, many young tubers are cut off when the soil is disturbed and drawn up to the plants. Immediately the soil is ridged the young runners begin to permeate the centre of that ridge where there is most moisture. From this stage onwards the progress of the new tubers is rapid simply because they are placed in a suitable medium. But if the earthing is put off too long the new tubers remain partly exposed or too near to the surface and do not attain normal size. Where the soil is stiff the ridge should be sharp to throw off heavy rains; where it is light, the ridge should be, approximately 4ins. across.—G.

SPROUTING BROCCOLI.

AMPLE proof that the broccoli has fought its way successfully into favour is found in the extensive list of varieties now on the market. Among others, sprouting kinds are mentioned; these, at their present-day standard, are of high merit and prove among the most profitable vegetables to grow.

Best of all is the Early White Sprouting. Sown in succession from early in March until June, they are capable of furnishing a continuous supply of curds from autumn until well into the winter, the late crops depending very much on the weather. The curds of well grown specimens are large, firm and of the best quality; and, then, each plant produces a very large total crop. Almost equally good is the Purple Early. This variety loses in colour, but is otherwise as good as the white; it is, again, superior to, but not so hardy as, the ordinary Purple, the curds being firm, compact and of fine flavour. The ordinary Purple is among the hardiest of winter greens, passing almost unaffected through severe weather in an apparently dormant stage, it grows whenever the weather improves, and so furnishes a welcome supply through the early months of the year,

Lastly, we may mention the newer Perennial White. With care and good feeding, this variety goes on in bearing for four or five years and yields from four to eight large and good curds annually, in addition furnishing a varying quantity of small but useful curds. It is at its best, however, during the first two or three years, and so new stock ought to be raised regularly, and older, less useful plants discarded.

Two points we may mention in growing such broccoli—plant firmly and allow plenty of space.—LANARKSHIRE.

SOW MORE SPINACH.

SUMMER spinach is such a quick-maturing crop and so easy to grow if seed is sown in well matured ground that arrangements should be made for a sowing every three weeks. It is wasteful and useless to do so thickly, as it is imperative that plants have room for development. Spinach loves moisture, and benefits if rotted farmyard or horse dung is incorporated with the soil and the hoe is kept frequently employed between the rows. A time of drought invariably is followed by plants running to seed. When this occurs they should be dug in and another sowing made. The average gardener, however, appears to be content with one or two sowings at the most, and one sometimes notices rows of plants which have gone to seed allowed to remain, whereas if they are turned in and more seed sown, another crop soon follows. The importance of treating spinach as individual plants, and less like mustard and cress, is not generally appreciated; but a minimum of 9ins. apart after the final thinning should be aimed at. Broadcast sowing appeals to some, but plants in drills are more easily dealt with. During a hot dry spell watering should be done frequently, and it is well to remember that spinach is quite satisfactory if sown between peas and other crops that give a partial shade. Victoria is still one of the best round-seeded varieties for sowing now.—W. F.

MISCELLANEOUS

THE WEED PROBLEM.

ALTHOUGH weeds are so troublesome to the gardener, the lusty growth of the wildings is not a wholly bad sign. If land will grow the weeds well it is certain that it will be capable of supporting useful crops of one kind or another. Weeds enter the garden in many ways. Birds will carry a few of the seeds, the wind will be responsible for still more, while, it is safe to presume that many are brought with manure and other material. It is a safe rule never to neglect to deal with weed growth, as, in warm damp weather, the plants grow apace. This is especially true in the case of the annuals, such as chickweed, groundsel, shepherd's purse, etc. Always attack the plants before they have a chance to set seed, and in this way prevent trouble in the future. On open patches of soil one can get at the weeds with a hoe and this method is useful from the cultivation standpoint. Weeds cannot be hoed directly from rows of other plants, and here they must be hand-pulled. It is best to deal with the weeds during a dry spell, as they then wither quickly. The annual weeds can be safely buried in a trench that is 2ft. or 3ft. deep and then covered with soil, or they may be burned. Do not stack up the weeds in a heap and leave them, for it is quite likely that the plants may succeed in developing and ripening seed, even under such unfavourable conditions.

The biennial and perennial weeds, such as dandelions, docks, thistles, couch grass, etc., are not so easy to get rid of. Here a good deal of care is needed to ensure eradication. As hoeing is not of much use, the ground should be dug, when possible, to the depth of quite a foot, and every little piece of root should be picked out. This may seem a tedious business, but it is the only way to clear the land. These weeds should never be buried, as they are extremely tenacious of life. The only way to deal with them is to place them on one side to dry and then burn them. Naturally, the ash which is derived from the burning of weeds represents the minerals which have been taken from the soil by the plants, such as potash, phosphorus, lime, magnesia, sulphur, etc., and it may profitably be returned to the land again.

Throughout the summer keep a sharp look-out for individual weeds which may start growth in some odd corner. These are often the source from which large numbers of plants will develop at a later date. An effective way of dealing with a big dock, or any similar plant, is on the following lines: Cut away the top of the plant, scooping out the upper part of the root in a hollow. Into this place salt or a little "Acme" weed-killer in powder form, and no further trouble will be experienced with that plant. Quite a number of weeds can be quickly treated in this way, and the bother of digging them up is avoided.

Weeds on paths are often the cause of a great deal of trouble. The old-fashioned plan of getting out the weeds with a knife is tedious and not by any means a sure cure. Salt sprinkled on a path certainly kills the weeds, but it often tends to make the ground damper, so that ultimately the growth of weeds is more vigorous than ever. By far the best plan is to use one of the excellent weed-killers now on the market. In using these weed-killers, take great care to follow the directions given, as it is essential that the solution should be applied at the proper strength. It should be pointed out that most of the common weed-killers are poisonous, and must, therefore, be handled with care and kept out of the way of children and animals. An exception is found in McDougall's "Perfect Safety," which is quite free from any dangerous properties. Weed-killers are best distributed on paths by means of a can with a spreading rose. It is only necessary just to cover the surface of the ground with the liquid. Remember that the weed destroyers do not possess discriminating powers and the liquid must be kept from plants which happen to border the paths. It is not a bad plan to protect the edging, whatever it may be, with a plank on either side while the weed-killer is actually being applied. While using the weed-killers wear gloves and do not allow the liquid to get on to clothes or boots. Never allow poultry to run over a treated path until three or four days have elapsed. As well, pet animals like cats and dogs, should be kept away from the paths for a similar period.—S. LEONARD BASTIN.

SPRAYING.

An Important Summer Operation.

NOT only is it necessary to bring to a speedy cessation the ravages of plant and shrub pests, but every effort ought to be made to ensure that the foliage, the lungs of the plant, is kept clean and free from dust or other adhesive material. Most summer insecticides, therefore, have a cleansing effect, and their use is a guarantee of health and vigour in the subject treated. Spraying during summer is a strong step towards good results, but it must never be overlooked that the best time to use a spray fluid is when attack first becomes apparent, or when the trees look sickly. As with most things, prevention is better than cure, so the man with a small confined garden finds it advisable to make a point of spraying early, indeed, even before parasites become noticeable. Spraying costs little and gains much.

Spray in the evenings and during dry weather. Employ a syringe which enables the fluid to be applied from above and below, and, as a rule, spray with a fine mist so as to coat the leaves above and below with a thin film of the liquid. Apply the fluid twice preferably, or, better still, thrice, at a few days' interval, and dilute the concentrate with water slightly warm: this point is seldom mentioned, but it is found that water at 80° Fahr. to 90° Fahr. is twice as effective as cold water.

In the absence of pests, or, at least, if the pest is only aphis, apply soapy water containing 2 oz. of soap or near that per gallon. Naphtha, disinfectant or nicotine soaps are best. If hard soap is used, boil first in a little water until dissolved. If the parasites have reached a stage of intensive and extensive destruction, use nicotine or arsenate or lead, of a compound of equal efficiency. Nicotine and arsenate are poisons, however, and they should not be used within one month of harvesting fruit.

In the past, growers did not take kindly to the making up of elaborate washes; but the necessity for that has passed. For a small sum, concentrates may be purchased, and all that is necessary is to dilute these with water. In the measuring out of water, if the capacity of a can is not known, remember that a gallon of water weighs 10lb.; a little over or a little under the measurement is not a serious matter. With everything favourable, then, there is no reason why one should not spray and every reason why one should. —H. A.

HEDGE TRIMMING AND MANAGEMENT.

FEW things show the effects of neglect more than the hedge, and it is essential that pruning and clipping should be carried out at the right time. In most cases, clipping should be done after the summer shoots make their appearance—that is, from the end of June to the middle of July. If the shears or knife are used too soon, a second treatment at the close of the summer may be needed. Hedges of holly and yew are best clipped early in September. When dealing with hedges formed of privet, hawthorn, yew or hornbeam, where the leaves are comparatively small, a pair of ordinary hand shears will be found to be the best. For laurel, viburnum and, in fact, all large-leaved subjects, shears must not be employed, as these will cause too great mutilation of the leaves. Here careful pruning with the knife is required. In shaping any hedge it is most important to cut so that the outline is roughly that of a pyramid, that is, wide at the bottom and narrowing towards the top. If, as so often happens, the lower

Digitized by Google

part of the hedge is cut closely back, the result is a thin growth, and quite often large gaps appear. A hedge that is properly grown and trimmed ought to be as effective a barrier as a fence.

The treatment of young hedges calls for special comment. Thorns should be cut nearly to the ground the first year, and all kinds of recently set hedges will be all the better for a severe pruning which will encourage a thick growth at the lower part. As the years pass the pruning should be less severe, and the hedge can be kept in good condition by an annual trimming. It should be remembered that young hedges are much helped by keeping the soil open round the roots, with a hoe or a fork, and weeds should be cleared away as soon as these put in an appearance.—L. B.

THE VALUE OF HOEING.

SOME people do not as yet appreciate the value of hoeing in the garden, in relation to drought. Mentioning the use of the hoe a while ago, I was surprised to find that it was still looked upon by many people simply as a weed destroyer. The value of the hoe in creating a surface mulch of loose soil can scarcely be over-estimated. Water which rises in firm soil passes from particle to particle until it reaches the surface and evaporates. If the surface soil be loosened, then the water cannot rise in it, because the soil particles are not close enough together to attract the water upwards.

Of course, the loose soil mulch which we leave dries out very quickly, but that is of small account so long as the soil below is kept moist. Now, that raises another question. How deeply should we hoe? One finds various depths advocated, but experiments have shown that, in England, 2ins. gives the best results. As to whether the Dutch hoe or draw hoe should be used is a matter of conditions. Where possible, I always use the Dutch hoe, as it leaves a better tilth and there is no need to walk over the soil one has loosened; but, of course, on hard and heavy soil the draw hoe is easier to manipulate, especially if a rather heavy one is chosen. As a matter of fact, where the soil has got somewhat baked, I have sometimes found it necessary to use a stock hoe (variously known as Canterbury hoe, tomahawk or double hoe) to make any impression.

As an illustration of the value of hoeing, I would just like to give one example: In a certain place in the Midlands, two allotments, side by side, were sown with carrots on the same evening, seed from the same packet being used. One plot was continually hoed throughout the summer, while the other was only hoed occasionally to keep down weeds. Very little difference was noticeable until drought set in, when the unhoed—or, rather, occasionally hoed—plot began to suffer. The other, regularly hoed, plot did suffer, of course, but not to the same extent. In fact, the carrots managed to struggle through the drought, and then, when rain did come, of course they soon grew away, with the result that a crop was obtained, while those on the other plot were beyond redemption before rain came. Finally, if dry weather does set in, keep the hoe going—it is far cheaper than water.—N. D. H.

REPAIRING A WATERING POT.

QUITE a good repair may be effected in a watering pot that has one or more holes in the bottom in this way. Fit a piece of sacking which is a trifle larger all round than the inside of the can. Now make up a little cement with water until it is the consistency of batter. Stand the can on a level surface and pour in the cement solution until the sacking is covered with a thin layer. Keep the can in the same position until the cement has set, and it is then ready for use. The cement adds very little to the weight of the can, and it often gives a new lease of life to a watering pot that otherwise would have to be discarded altogether.—S. LEONARD BASTIN.

STONE ORNAMENTS AND FURNITURE.

A GARDEN, however well designed and tastefully planted, seems to be incomplete without garden ornaments and furniture of some kind. These should be in keeping not only with the style of the garden but with the character of the house also. They add in no small degree interest, beauty and comfort to any garden. Furniture or ornaments of fantastic design should, above all, be avoided; simplicity and proportion must be carefully studied if the garden is, as a whole, to be restful and pleasing to the eye. Few can go wrong if they select ornaments and furniture made of natural stone. These

ORNAMENTS AND FURNITURE OF BATH STONE.

are suitable for practically all types of gardens. The colouring of natural stone blends well with any colour scheme, and for durability stone of this kind heads the list. There are many substitutes for natural stone on the market, but, of course, the latter comes first and foremost.

Semicircular stone seats, large vases, a dove-cote or a sundial can all be used in the same garden: in fact, a small formal garden constructed practically of stone and enclosed by a balustrade is most effective. Specimen plants of hydrangeas, fuchsias and rhododendrons are shown off to their very best advantage when grown in large tubs made of stone, and either square or round in shape.

From many points of view Bath stone is one of the best for this kind of work. Its colour, surface and lasting qualities are superior to other types, and furniture of simple and artistic design made of this stone is a great asset to the garden. The seats and ornaments of Bath stone which are constructed by the Horsecombe Quarries and Stone Works, in the neighbourhood of Bath itself, are of excellent design, and so varied that they are suitable for every size of garden. They make quaintly designed dove-cotes, pedestals, vases, benches and seats, which even in themselves are attractive, and when placed in a garden they will be a source of pleasure for years to come, lending beauty to their surroundings.

THE CARBOLINEUM WASHES.

FROM general results obtained in many parts of the country, and from the reports and remarks of authorities, it appears safe and even desirable to recommend the use of carbolineum washes for fruit trees.

The claims made for the washes are—and they have been substantiated in many cases—that they kill the eggs of many insect pests in addition to cleansing trees of the green vegetable growths on the bark.

The first result I saw from their use was conclusive in one respect—that it is dangerous to apply them after the buds have begun to show the least sign of growth; in the case under review practically every bud showing growth was either crippled or killed.

The second conclusion I reached was that the claim advanced as an insect egg destroyer was more than partly correct. Eggs of the apple sucker, aphis and caterpillar failed to produce any living organism, but eggs of the capsid bug appeared to retain their vitality unimpaired. Since this result three years ago, many other trials have been carried out, not only with the original preparation, which was a foreign one, but also with several British preparations. Most of the results support my earlier conclusions.

So far, then, we are safe in recommending a carbolineum wash in preference to a caustic soda one, because caustic soda, if it destroys any insect eggs at all, the number destroyed is negligible, and the carbolineum washes are just as effective in their cleansing the trees of vegetable growths.

All this in favour of the new washes, but a question arises which has not yet been satisfactorily answered—the effect of yearly applications. It is stated that annual applications are likely to cause much irritation to the bark of the trees, causing a softness which becomes susceptible to the ingress of fungoid spores.

Finally, then, the course to follow at present is to use a carbolineum wash in preference to a caustic soda one, but not to apply yearly applications until more conclusive evidence is obtained regarding the effect on the bark of trees.

There are several of the washes on the market and any of the well known firms supplying insecticide will be able to execute your order.—H. C. ELSDON.

PUBLICATIONS RECEIVED.

"Lime in Agriculture," by Frank Ewart Conis (Chapman and Hall, 3s. 6d. net). A handbook for practical farmers, students and others.

"Every Man His Own Gardener," by John Halsham. (Hodder and Stoughton, 6s. net.) A new and revised edition of this helpful contribution to gardening literature. It is packed full of information on all gardening topics, and all amateur gardeners will find it both interesting and instructive.

"Goldfish Culture for Amateurs," by A. E. Hodge and Arthur Derham. (H. F. and G. Witherby, 5s. net.) An interesting account of how to breed and rear goldfish in aquaria and ponds.

"Key to the Families of the Dicotyledons" taken from The Families of Flowering Plants, by J. Hutchinson. (Messrs. Macmillan and Co., price 2s.) A valuable handbook for all botanical students and scientific horticulturists.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

AMONG THE VEGETABLES.

The last sowing of beet should be made, and the earlier crops thinned to a few inches apart unless it is the turnip rooted variety, when little or no thinning is needed beyond the removal of the largest roots for the kitchen, as required. Carrots can also be thinned, and if the crop is a poor one, a further sowing of a stump-rooted variety may be made. A late sowing often escapes the carrot fly, and, moreover, young tender roots are always appreciated. Coleworts are not grown so much as their merits deserve, and if seeds are sown now plants will be ready for the kitchen about October, while another sowing made a few weeks hence will furnish a supply for the winter. Dwarf beans are making headway, but, unfortunately, they are often overcrowded, a foot apart is none too great. They will quickly cover this space, and produce a fine crop. If seeds of asparagus were sown some weeks ago, the seedlings will be sufficiently advanced for thinning to 3ins. or 4ins. in the lines. Any blank spaces can be filled by the thinnings if they are carefully lifted with a small hand fork. This crop should be encouraged by frequent hoeing, then the young plants will be ready for their permanent quarters next spring. Tomatoes outside should have all their side growths removed, kept tied up to the wall or stakes, and the main or principal leaves left intact. The mutilation of these ought not to be practised.

HERBACEOUS BORDERS.

These require almost constant attention, the hoe must be used frequently, plants past their best cut down or made tidy, and others afforded stakes before they are beaten to the ground by wind or heavy rain. Asters and Michaelmas daisies are so valuable in the autumn, that they deserve special attention, and although not a strict advocate for single stems, certainly each clump should be reduced to six or seven growths. Chrysanthemums ought also to be given support early before the shoots are injured. Annuals sown in borders are usually too thick and if good specimens are needed each plant must be allowed ample space for development. It is best to perform the operation of thinning at short intervals until the plants are strong, otherwise slugs may finish off those that are left.

FRUIT TREES ON WALLS

On both plums and peaches green and black fly appear to be on the increase, and in some gardens the young shoots are injured by these pests. Syringe or spray with quassia extract, and see that the curled leaves are thoroughly wetted. If we experience a dry, hot spell of weather it will be advisable to give water liberally. Newly planted trees must be watched for dryness at the root and if late planting was practised, the trees ought not to produce any fruit this season. This year many peach trees are overburdened with fruit and I have found few amateurs who will reduce the number so that good quality fruit is obtained. Much of the fruit should have been removed before this date, but many trees are still overcrowded, and in consequence they should be gradually reduced until they are about 6ins. apart.

RASPBERRIES.

In two gardens recently I saw beds of raspberries which were planted last winter, and an effort was being made to secure a crop of fruit this summer. Now this is asking too much, and any canes in a similar condition should be cut down to within a few inches of the ground. The object is to secure strong young canes during the present growing period, and these will produce a good crop in 1927. Established plantations are pushing up a quantity of new growths, and these must be reduced to about six of the best on each root, or stool.
